

**A WIRELESS SYSTEM FOR COMMUNICATING
CASHLESS VENDING TRANSACTION DATA AND
VENDING MACHINE AUDIT DATA TO REMOTE
LOCATIONS**

RELATED APPLICATIONS

This U.S. non-provisional application is a continuation-in-part application that claims priority of a U.S. non-provisional application, Serial No. 09/884755, inventor H. Brock Kolls, entitled SYSTEM FOR PROVIDING REMOTE AUDIT, CASHLESS PAYMENT, AND INTERACTIVE TRANSACTION CAPABILITIES IN A VENDING MACHINE, filed June 19, 2001; which is a continuation in part application that claims priority of a U.S. non-provisional application, Serial No. 09/888797, inventor H. Brock Kolls, entitled A METHOD OF PROCESSING CASHLESS PAYMENT TRANSACTIONS WORLDWIDE, filed June 25, 2001.

TECHNICAL FIELD OF THE INVENTION

The present invention relates to a system that is scalable and configurable to include vending equipment audit capabilities, a card reader assembly having a card reader processor interface board for accepting card identification data as payment for items vended, an interactive interface and protocol for interconnecting the system to a computing platform, and support for a plurality of communication options that include wired, point-to-point wireless, and wireless wide area networked (WAN) solutions. In

addition, the present invention also relates to a system and method of effectuating a payment device for accepting card ID data, authorizing the validity of the card ID data, facilitating a vending transaction, settling the transaction to effect payment for the vended goods and services, gathering DEX and MDB audit data from the vending equipment, and data communicating with a plurality of remote locations where a remote location can be a global network based data processing resource.

BACKGROUND OF THE INVENTION

Recent trends in the vending industry have been to offer higher priced item out of vending equipment at traditionally unattended vending locations. Higher priced item offers can result from the desire to vend larger portions of products such as the twenty-ounce soda bottle verse the twelve-ounce soda can. In other cases the higher priced items can be items that until recently my not have been consider for sale through vending equipment such phone cards, disposable cameras, and frozen food entrees to name a few.

The vending industry's desire to vend higher priced items has given rise to issues related to currency and inventory. For example, with the shift to vending twenty-ounce bottles many of the vending sales now involve more that one currency note, as an example two one-dollar bills to make a purchase. As a result the bill validator can fill to capacity with currency notes before all the items in the vending equipment have been sold. With a bill acceptor filled to capacity the vending equipment may not be able to transact another vending sale and place itself out-of-service. As a result vending operators can typically find themselves restocking vending equipment that still has product available for sale but because of the inability to take additional currency notes the vending equipment could not sell the inventory.

In addition, with many beverage type vending machines the shift from the twelve-ounce can to the twenty-ounce bottle can create coin mechanism issues. In moving to the larger size beverage the average price can move from typically slightly less than a dollar where little change was required when a dollar note was used for payment to slightly
5 more than a dollar where the better part of a dollar in change can be required when two one-dollar notes are used for payment for a vend. Resultant from this price move not only do the bill validators fill to capacity faster and stop working sooner, but the coin mechanism can be required to supply a customer with more change on each vend depleting a coin mechanism coin supply faster. Once the coin change supply is depleted
10 the vending machine may be rendered out-of-service.

In addition to the new burden on bill acceptors and coin mechanisms resultant from the sale of higher priced items other issues related to the vending of higher priced items can arise. One such issue can be that a customer may not have enough money on-
15 hand to effectuate the vending purchase. In the case of phone cards, cameras, and frozen food vend prices may range from several dollars to forty dollars, fifty dollars, or more. In many cases the customer may have the desire to purchase the high priced item but simply lacks the amount of currency required to effectuate the purchase. In other cases the customer may be reluctant to trust the vend worthiness of the vending equipment with
20 what the customer considers to be a significant amount of money.

As the proliferation of higher priced vend items continues to become more pervasive in today's society the vending industry has become increasingly concerned about tracking inventory and the operational status of the vending equipment remotely. It
25 is considered a general belief within the vending industry that remotely monitoring vending equipment can optimize a route driver's daily activity and reduce operational costs associated with the sales and delivery of products to the vending equipment.

To date auditing devices have been designed to be placed inside the vending equipment or held in the hand of a route collector for the purpose of gathering vending equipment inventory and operational data which can later be downloaded to a computer. These devices however have been costly to manufacture, install, maintain, and operate.

5 As such the total cost of the technology verse the savings on the operational costs associated with the sales and delivery of products to date have not made for a sound or compelling business model. As a result the vending industry has been slow to adopt 'audit' only technology.

10 The cost benefit model of the 'audit' hardware may not be the only issue hampering the proliferation of 'audit' only device. Data communication costs, the costs of getting the data back to a central computer center can be a significant limitation on getting vending equipment remotely 'audit' capable or as it is commonly referred to in the vending industry as 'online'.

15 Such telecommunication costs can include the cost of running a telephone line to the vending equipment. In many cases the vending equipment may be in a location not conducive to having a dedicated phone line installed proximate to the vending equipment, such as in a concrete basement, on a golf course, in a shopping mall, or on a university
20 campus to name a few. Once a telephone line is installed there can be monthly service charges incurred from the telecommunication company providing the service. These costs alone can in effect nullify the savings of having the vending equipment 'online'.

25 To avoid the high expense of running dedicated telephone lines to vending equipment the vending industry has pursued wireless wide area network (WAN) options. Implementing a wireless WAN has typically involved purchasing additional wireless hardware, and trying to integrate the wireless hardware with the 'audit' hardware. If the integration effort was successfully the hardware, service, and maintenance costs of the

combined solution were typically significantly increased compared to the 'audit' device only solution costs. In addition, the service and maintenance required for the combined wireless system is typically different then the non-wireless 'audit' device only solution.

5 In addition to the increased hardware costs for the wireless WAN solution, the wireless communication service fees paid to the wireless network provider can be more than those fees charged by the communication companies providing telephone line service. A technology solution and service fee structure that could effectively nullify the anticipated sales and delivery savings from having the vending equipment 'online'.

10 In part a long felt need exists for a solution related to a cost effective system and method for remotely auditing vending equipment, and for providing additional payment options at the point of sale for goods and services vended from vending equipment. This coupled with the industry's shortcoming in these areas and other areas, some of which
15 were mentioned above give rise to the present invention.

SUMMARY OF THE INVENTION

20 The present invention relates to a system that is scalable and configurable to include vending equipment audit capabilities, a card reader assembly having a card reader processor interface board for accepting card identification data as payment for items vended, an interactive interface and protocol for interconnecting the system to a computing platform, and support for a plurality of communication options that include wired, point-to-point wireless, and wireless WAN solutions.

25 The present invention also relates to a system and method which effectuates an interactive interface and protocol for interfacing the system to and data communicating with a computing platform, wherein the computing platform can elect to control by way

of the interactive interface and protocol the vending transaction cycle or alternatively elect to monitor the system by way of the interactive interface and protocol allowing the system to control the vending transaction cycle.

5 The present invention also relates to a system and method of effectuating a payment device for accepting card ID data, authorizing the validity of the card ID data, facilitating a vending transaction, settling the transaction to effect payment for the vended goods and services, gathering DEX and MDB audit data from the vending equipment, and data communicating with a plurality of remote locations, where a remote location can
10 be a global network based data processing resource.

 The present invention also relates to a system having a plurality of configurable communication options for data communicating to a plurality of remote locations. Such communication options include local area network connection, telephone line, wireless
15 point-to-point where the system data communicates wirelessly to a local transceiver base unit which has access to a telephone line thereby give the system wireless access to a telephone line, and wireless network data communication access, wherein a data modem connects the system to a WAN for data communication access to a plurality of remote locations.

20 The present invention also relates to a system and method for implementing an MDB protocol gateway for the purpose of supporting a plurality of peripheral devices each of which may be implementing a different version of MDB protocol then the vending equipment's vending machine controller (VMC).

25 The present invention also relates to a system and method for authorizing and settling card transactions with a processing bureau where the authorization process can be performed by the system locally eliminating the need for data communication with a

remote processing bureau, and for processing international card transactions from a single country, wherein international currency conversion processing fees are minimized.

The present invention also relates to a store and forward data network system and method, wherein data gathered at a central server from a plurality of remote systems installed in a plurality of vending equipment is converted as required and made available to a plurality of other servers for the purpose of using the data to manage a vending business and or supplying data to a backend management system.

The present invention also relates to the system 500 being packaged in semiconductor creating a single chip system 500 solution.

BRIEF DESCRIPTION OF FIGURES

The present invention is best understood from the following detailed description when read in connection with the accompanying drawings. Included in the drawings are the following Figures:

Figure 1A-1B there is shown a vending machine interface unit 100;

Figure 2 there is shown a transceiver and modem base unit 200;

Figure 3A there is shown a front view of a card reader assembly;

Figure 3B there is shown a left side view of a card reader assembly;

Figure 3C there is shown a right side view of a printer assembly;

Figure 3D there is shown a front view of a printer assembly;

Figure 3E there is shown a right side view of a card reader assembly and a right side view of a printer assembly being aligned for assembly together;

Figure 14 there is shown an international transaction authorization and settlement routine 1400;

10 Figure 15 there is shown a data communication transaction message parsing routine 1500;

Figure 16A-16B there is shown a determination of transaction completion routine 1600;

15 Figure 17 there is shown a data communication sweeping, processing, and data forwarding routine 1700;

20 Figure 18A-18B there is shown a mimic MDB interface port routine 1800;

Figure 19A-19B there is shown a local authorization database management routine 1900; and

25 Figure 20 there is shown a transceiver and modem base unit system 700 wireless protocol data communication routine 2000.

DETAILED DESCRIPTION OF THE INVENTION

Referring to Figure 1A and 1B there is shown a vending machine interface unit (VIU) 100. Figure 1A shows an antenna 124 mounted perpendicular to the enclosure's main body. Figure 1B shows the antenna 124 mounted parallel to the enclosure main body. In an exemplary embodiment, antenna 124 is included in embodiments making use of the wireless VIU 100 connectivity and excluded in embodiments not requiring wireless VIU 100 connectivity.

The VIU 100 is a control system that interfaces to a plurality of different kinds of vending machines by way of a plurality of different interface ports. One such interface port can be the NATIONAL AUTOMATED MERCHANDISING (NAMA) vending industry MULTI-DROP-BUS (MDB) interface. Other MDB interfaces can include derivative MDB bus specifications, where a derivative MDB bus specification can be one that support less than all the NAMA standard, or augments the NAMA standard with additional protocol commands and or features. A second such interface port can be the EUROPEAN VENDING ASSOCIATION'S vending industry DATA EXCHANGE INTERFACE (DEX) interface. Additional interface ports include serial and pulse style bill validators, and coin mechanism interfaces.

Vending machine types suitable for interconnection to and operation with the VIU 100 include vending beverage and snack machines, value adding equipment, and dispensing equipment that operates in connection with or makes available a MDB bus interface, or DEX interface, or a bill acceptor interface, or a coin mechanism interface. Such vending machines include for example and not limitation those manufactured by or for COKE-A-COLA, PEPSI, MARS, VENDO, ROYAL, DIXIE NARCO, GPL, CRANE NATIONAL, AUTOMATED PRODUCTS, CAVALIER, MARCONI or other similar vending machines. Such value adding equipment and dispensing equipment can include

for example and not limitation those manufactured by or for ACT, XCP, SCHLUMBERGH, DAYNL, DEBITEK, GILBARCO, MARCONI, COPICO, PRE-PAID EXPRESS, or other similar value adding equipment and dispensing equipment.

5 For purposes of disclosure the term vending machine, value adding machine, and value dispensing machine can be referred to as a vending machine, vending equipment, and or vender. Other vending machine can include copiers, fax machines, public access personal computers (PC), data ports, and other types of office products or business center types of equipment.

10 Audit-credit-interactive system 500 electronics are included within the VIU 100. For purposes of disclosure a system 500 can be referred to as a vending machine interface unit, VIU 100, or audit-credit-interactive system 500. Many of the electrical interfaces, ports, and connectors shown in Figure 1A and 1B are actually electrical connection to the
15 audit-credit-interactive system 500 (system 500).

The vending machine interface unit (VIU) 100 includes an interactive interface port 102. The interactive interface port 102 provides an electrical connection to the interactive interface 532. In an exemplary embodiment the interactive interface port 102
20 enables other computing platforms to interface to and operational work with the vending machine interface unit 100. A computing platform is a microprocessor based system and can include the card reader interface processor board 312, the card reader and user interface system 600, or personal computer (PC) based systems. In addition a computing platform can include INTEL, MOTOROLA, MICROCHIP, AMD, UBICOM, ZILOG,
25 IBM brand or other similar microprocessor based systems. A computing platform can operate on a plurality of operating systems including, assembler based, proprietary systems, MICROSOFT, LINUX, QNX, WIND RIVER, J9, BLACK DOWN, and other JAVA VIRTUAL MACHINE (JVM) based or other similar or suitable operating system.

VIU 100 also includes auxiliary interface port 104 and 106. Though general purpose in nature in an exemplary embodiment Ports 104, and 106 provide electrical connections to printer interface 532, and external modem interface 528 respectively. The

5 Ports 104, and 106 can be RS232, RS484, or other desirable type of communication interface port. Furthermore ports 104, and 106 can be configured for use as required by the desired application. In an exemplary embodiment auxiliary interface port 104 can be used for interfacing to a serial style printer and port 106 can be used to interface to

10 external communication equipment such as data modem, CDMA modems, CDPD modem, wireless transceivers, wireless systems, or other types of communication devices. In an exemplary embodiment an AES wireless transceiver or other private radio network can be used to provide data communication to and from the VIU 100 as well as serve as repeater to receive and re-transmit data communication to and from other VIU

15 100 types of devices in the geographic area.

The VIU 100 includes a MULTI-BUS-DROP (MDB) interface port 108, and a DATA EXCHANGE INTERFACE (DEX) 112. MDB port 108 and the DEX port 112 provide electrical connections to the MDB interface 518, and the DEX interface 520 respectively. The electrical characteristics and operation of the MDB port 108 are

20 detailed in the NATIONAL AUTOMATED MERCHANDISING ASSOCIATIONS industry specification entitled MDB/ICP INTERFACE PROTOCOL version 1.0 and version 2.0. The electrical characteristics and operation of the DEX port 112 are detailed in the EUROPEAN VENDING ASSOCIATIONS EVA-DTS specification version 4.0, and 5.0. MDB interface 518, DEX interface 520, bill and coin interface 506, mimic MDB

25 interface 516, and office products interface 534 can be referred to as peripheral device interfaces.

The MDB interfaces allow the VIU 100 by way of the MDB interface 518 and MDB port 108, to be original equipment manufactured (OEM) into or retrofitted into vending, valuing, and dispensing equipment that provide an MDB bus interface. Furthermore, the VIU 100 by way of the DEX interface 520 and the DEX port 112, can be original equipment manufactured (OEM) into or retrofitted into vending, valuing, and dispensing equipment that provide a DEX interface.

VIU 100 includes card reader interface ports 110, and 114. The card reader ports 110, and 114 provide electrical connection to the card reader interface 526. Card reader interface ports interface to industry standard bit strobe, and serial style track 1, 2, and 3 card readers. Such card readers include for example and not limitation those manufactured for or by XICO, NEURON, MAGTEK, as well as compatible card readers manufactured by other companies.

The VIU 100 also includes an RJ11 jack 116. The RJ11 jack provides electrical connections to the modem 522. In an exemplary embodiment the RJ11 jack 116 interconnects the VIU 100 to a telecommunication line, wherein data communication can occur between the VIU 100 and a plurality of remote hosts networks and locations.

VIU 100 also includes a general-purpose input-output interface 118. The general-purpose input-output interface provides electrical connections to the bill and coin interface 506. In an exemplary embodiment the VIU 100 can be interconnected with vending, valuing, and dispensing equipment by way of the host equipment's bill acceptor or coin interface port. This allows the VIU 100 by way of the bill and coin interface 506 and interface 118 to be original equipment manufactured (OEM) into or retrofitted to vending, valuing, and dispensing equipment that utilize a serial or pulse style bill acceptor, or a coin mechanism interface. Serial and pulse style bill acceptors include for

example and not limitation those manufactured for or by MARS, COINCO, CONLUX, ARDAK, or other similar bill acceptor and manufacturers of bill acceptors.

The VIU 100 includes a service button 120 and a ground terminal 122. The service button provides one of a plurality of electrical connection to the keypad and button inputs 510. The ground terminal 122 provides, as may be required, electrical connection to the VIU 100 enclosure.

Antenna 124 can pass through the VIU 100 enclosure or be mounted to the VIU 100 enclosure. The antenna 124 provides an antenna electrical connection to the transceiver 524, data modem 514, or optionally an antenna electrical connection to an external modem interconnected with auxiliary interface port 106.

Referring to Figure 2A and 2B there is shown a transceiver and modem base unit 200. Transceiver and modem base unit 200 includes transceiver unit 700 built in. The transceiver unit 200 with transceiver unit 700 data communicates wirelessly with the VIU 100 and by way of a modem data communicates with a remote location. In an exemplary embodiment the VIU 100 with system 500 and transceiver unit 200 with transceiver unit 700 form a wireless data link, which has access to a modem for data communicating with a remote location. In this regard the reliance on having a telecommunication line in proximity to the VIU 100 or more generally in proximity to the vending equipment the VIU 100 is installed in is greatly reduced.

A remote location can be an Internet based resource, or Internet based data communication. Internet based connections and resources can be referred to as a global network based data processing resource. For purposes of disclosure a remote location can be referred to as an Internet connection, or a global network based data processing resource. A global network based data processing resource is a remote location.

The transceiver unit 200 has incorporated into it a system 700 control system. Figure 2 shows a telecommunication access port 202 in the side on the transceiver unit 200. The telecommunication access port 202 provides access by way of a plurality of electrical connections to the modem 704. A telecommunication access port 202 can be an RJ11 style, or similar telecommunication connector.

Attached to the transceiver unit 200 is an antenna 716. The antenna 716 provides an antenna electrical connection to the transceiver 708. The antenna 716 can be an antenna manufactured by the ANTENNA FACTOR, or other similar or suitable antenna.

An indicator lamp is also viewable through an indicator port 204 in the transceiver unit 200 enclosure. An indicator lamp can be part of the transceiver system 700. Such an indicator lamp being viewable through indicator port 204 can be utilized to inform a user of correct operation of the transceiver unit 700.

The transceiver system 700 located inside the transceiver unit 200 enclosure can obtain power for operation from an electrical connection by way of AC connection 208. In an exemplary embodiment the AC connection 208 can be plugged into a standard 115VAC wall outlet.

Referring to Figures 3A and 3B there is shown a card reader assembly. Figure 3A shows a front view of the card reader assembly. Figure 3B shows a left side view of the card reader assembly. In an exemplary embodiment the card reader assembly can be installed in a vending machine. A user having access to the front of the card reader assembly can insert cards, view display information, use a push button to provide system input and if equipped with a printer assembly obtain a receipt, coupon, or other print information dispensed to the user.

5 A faceplate 302 is shown fastened to a support bracket 318. The faceplate 302 is sized to fit the industry standard bill validator opening, which can be found on most brands and models of vending equipment. The faceplate 302 has a plurality of holes to allow fastening of the card reader assembly into the vending equipment.

10 Faceplate 302 also has a paper exit slot 304 to allow receipt printer 328 to dispense a printed receipt to a user of the system. Faceplate 302 also has a display slot 306 which allows display 606 mounted on the card reader interface board 312 to be viewable from its mounting location behind the front surface of faceplate 302. Faceplate 302 also contains a plurality of threaded studs for mounting the card reader interface processor board 312.

15 In addition, faceplate 302 can be fastened to a bracket 318. Bracket 318 has a plurality of threaded inserts 320 for fastening a card reader 310 to the card reader assembly. The bracket 318 also has a threaded insert 316 located in the rear of the bracket 318. Threaded insert 316 can receive thumbscrew 334 in order to facilitate the fastening of the printer assembly bracket 330 to the card reader assembly.

20 A push button switch 308 can be fastened to the faceplate 302 and electrically connected to the card reader interface board 312 by way of cable assembly 336. In addition, card reader 310 can be electrically connected to the card reader interface board 312 by way of cable assembly 314.

25 Referring to Figures 3C and 3D there is shown a printer assembly. Figure 3C shows a right side view of the printer assembly. Figure 3D shows the front view of the printer assembly. In an exemplary embodiment the printer assembly can be slid onto the card reader assembly (see Figure 3F) and secured to the card reader assembly by way of

the thumbscrew 334. A card reader assembly having been equipped with a printer assembly can now print receipts, coupons and other print information for a user of the system.

5 At the top of printer bracket 330 there is a cutout for receiving a paper holder rod 324. The paper holder rod 324 is typically inserted through a roll of paper, such as paper roll 322. Printer bracket 330 also has a plurality of mounting holes to secure printer the mechanism 328 to the printer bracket 330. Printer bracket 330 has a threaded thumbscrew 334 secured to the bracket 330.

10 The printer mechanism 328 has a paper advance knob 326. The paper advance knob 326 can be used to position the paper.

15 Referring to Figure 3E there is shown a right side view of a card reader assembly and a right side view of a printer assembly being aligned for assembly together. In an exemplary embodiment a user of the card reader assembly can choose to add the ability to print receipts, coupons, and other print information by sliding the printer assembly onto the card reader assembly and making the appropriate electrical connections. Furthermore, the printer assembly can be securely fastened to the card reader assembly
20 by way of thumbscrew 334.

 Referring to Figure 3F there is shown a right side view of the assembled card reader and printer assembly.

25 Referring to Figure 3G and 3H there is shown a payment module. The payment module can be organized to provide scaled functionality. In general system 500 can be broken into modules of functionality and then combined as required by the application. In an exemplary embodiment a base level payment module may only implement the portion

of system 500 dedicated to the functionality of accepting a form of payment, interfacing to a vending machine, and interfacing to an external computing platform. A base level payment module may also make use of an LED display such as LEDs 340, 342, and 344 in lieu of a LCD type display to minimize cost. In addition, a base level payment module
5 may not support remote location communications options. Instead the base level payment module may make use of communications available by way of the computing platform the base payment module is interfaced with. This feature may further reduce the payment modules manufacturing costs. In other exemplary embodiments a display module and a communications module can be added to the base level payment module to offer
10 enhanced display and communications capabilities. Both the display module and communication module are a subset of electrical functionality of the overall system 500 design.

Referring to Figures 3G-3H there is shown a payment module assembly. In an
15 exemplary embodiment the payment module assembly can be installed in a vending machine's dollar bill validator slot. A user having access to the front of the payment module assembly can insert cards, view transaction status information via the three LED display (340, 342, 344), and use a push button 308 to provide system input. A faceplate 302 is shown fastened to a support bracket 318. The faceplate 302 is sized to fit the
20 industry standard bill validator opening, which can be found on most brands and models of vending equipment. The faceplate 302 has a plurality of holes to allow fastening of the card reader assembly into the vending equipment. A graphical instruction overlay 356 can be attached to the faceplate 302. Faceplate 302 also contains a plurality of threaded studs 346 for mounting the card reader LCD display board (not shown). An LED display
25 assembly comprising LED 340, 342, and 344 are viewable to a user. The LED display communicates status information related to the state of the vending machine or state of the card reader, as well as the status of a current transaction. In an exemplary

embodiment the function of the LED display and color of the LEDs can be selected and defined in accordance with EVA cashless payment guidelines for LED displays.

An interface connection 348 on the payment module board 350 provides an electrical interface to external data processing equipment and or other computing platforms. Such external data processing equipment and or computing equipment can include communication devices, display devices, telemetry devices, VIU's, interactive media devices, PC based platforms, and other types of computing platforms. Interface 348 can be an external peripheral interface 536, a network interface 542, an interactive interface 532, or other type of interface.

In addition, faceplate 302 can be fastened to a bracket 318. Bracket 318 has a plurality of bracket fasteners for fastening a card reader 310 to the card reader assembly. The bracket 318 also has a threaded insert 316 located in the rear of the bracket 318. Threaded insert 316 can receive a thumbscrew in order to facilitate the fastening of the printer assembly bracket (not shown) to the card reader assembly.

A push button switch 308 can be fastened to the faceplate 302 and electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component. LED display 340, 342, and 344 can be electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component. In addition, card reader 310 can be electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component.

In an exemplary embodiment the firmware embedded in the base level payment module could support base level functionality as well as other payment module functionality available with an expansion daughter board (i.e. display, communication, and other function modules). Such base level functionality could include: the MDB

Controller/G4 E-port/E-port (System 500) Interface Protocol And Specification, certified credit bureau protocol and transaction processing directly with credit bureau when communication options allow, local authorization card processing option, a self managing local databases for use during local authorization processing, setup mode to configure

- 5 MDB bus interface options and other card reader parameters and hardware options, DEX interface polling and data passing to USALIVE remote location and other remote locations when certain hardware options are available, communication support for modem, point-to-point, and external data modem when certain hardware options are available, active and passive modes of operation to support dial-a-vend, and other VIU
- 10 initiated transactions, and or full transaction management which includes the steps of: 1) Accept card for cashless payment; 2) check card local or remote authorization (remote authorization via external communications means); 3) conduct transaction (remotely manageable single or multi vend options, max vend item limits, time-out limits, max authorization amount limits, accrue sale amounts, time stamp transactions, save in non-
- 15 volatile memory transaction records); and 4) post process transaction (record inventory dispensed, and payment detail in transaction record, data communicate transaction information upon request to external communication platform).

- To allow functionality expansion of the base payment module which could
- 20 include printing options, communication options, electronic locks, and other vending machine interface options (such as DEX) a daughter board could be added to the base payment module. More specifically, additional payment module functionality through the use of one or more daughter cards could include: support for optional DEX interface, support for optional 16 character by 2 line LCD display or other types and styles of LCD
- 25 or vacuum florescent displays, support for optional printer circuit card; and support for optional communication card (communication card could support point-to-point, modem, and external modem interfaces).

Referring to Figures 3I and 3J there is shown how a payment module with communications daughter board, and optional LCD display could be incorporated into the base level payment module. Referring to Figures 3I and 3J there is shown a payment module assembly. In an exemplary embodiment the payment module assembly can be installed in a vending machine's dollar bill validator slot. A user having access to the front of the payment module assembly can insert cards, view transaction status information via the LCD display or the three LED display (340, 342, 344), and use a push button 308 to provide system input.

A faceplate 302 is shown fastened to a support bracket 318. The faceplate 302 is sized to fit the industry standard bill validator opening, which can be found on most brands and models of vending equipment. The faceplate 302 has a plurality of holes to allow fastening of the card reader assembly into the vending equipment.

Faceplate 302 also has a paper exit slot 304 to allow a receipt printer (not shown) to dispense a printed receipt to a user of the system. Faceplate 302 also has a display slot 306 which allows the LCD display mounted on the threaded studs 346 to be viewable from its mounting location behind the front surface of faceplate 302. An LED display assembly comprising LED 340, 342, and 344 are viewable to a user. The LED display communicates status information related to the state of the vending machine or state of the card reader, as well as the status of a current transaction. The function of the LED display and color of the LED can be selected or defined in accordance with EVA cashless payment guidelines for LED displays.

An interface connection 348 on the payment module board 350 provides an electrical interface to external data processing equipment and or other computing platforms. Such external data processing equipment and or computing equipment can include communication devices, display devices, telemetry devices, VIU's, interactive

media devices, PC based platforms, and other types of computing platforms. Interface 348 can be an external peripheral interface 536, a network interface 542, an interactive interface 532, or other type of interface.

5 In addition, faceplate 302 can be fastened to a bracket 318. Bracket 318 has a plurality of bracket fasteners for fastening a card reader 310 to the card reader assembly. The bracket 318 also has a threaded insert 316 located in the rear of the bracket 318. Threaded insert 316 can receive thumbscrew 332 in order to facilitate the fastening of the printer assembly bracket (not shown) to the card reader assembly. An expansion board 10 354 can be mounted to the bracket 318 and electrically interconnected to the base level payment module board 350 by way of cable assembly 356 or as a PCB mountable component.

15 A push button switch 308 can be fastened to the faceplate 302 and electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component. LED display 340, 342, and 344 can be electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component. In addition, card reader 310 can be electrically connected to the payment module board 350 by way of cable assembly or as a PCB mountable component.

20 Referring to figure 3K there is shown a payment module and printer assembly being aligned for assembly together. In an exemplary embodiment support for a printer option can be accomplished with the addition of a daughter card or interconnection of a printer mechanism with the base level card reader board 350, and the addition of the printer assembly. Shown in Figure 3K is a printer assembly plate 330, interconnected 25 with a paper roll holder 324, a printer mechanism 328, and a thumbscrew fastener 332. Also shown is a paper roll 322 being held by the paper roll holder 324 and a paper feed adjuster 326, which is part of printer mechanism 328.

In an exemplary embodiment a user of the payment module assembly can choose to add the ability to print receipts, coupons, and other print information by sliding the printer assembly onto the card reader assembly and making the appropriate electrical connections to the daughter board 226 or card reader card 350. Furthermore, the printer assembly can be securely fastened to the card reader assembly by way of thumbscrew 332.

Referring to Figure 4 there is shown a vending machine 402, vending machine interface unit 100, card reader with optional printer assembly 406, and transceiver and modem base unit 200.

In an exemplary embodiment a VIU 100 can be located inside the vending equipment, such as vending equipment 402. In addition the card reader assembly with optional printer assembly can be mounted inside the vending equipment in such a way that a user has access to the card reader assembly. During operation a communication line can be interconnected directly with the VIU 100. Alternatively the VIU 100 can wireless data communicate with a transceiver base unit 200. There is shown in Figure 4 a transceiver unit 200 plugged into an electrical outlet on wall 202. Also shown is a telecommunication line 408 interconnect with transceiver unit 200.

Referring to Figure 5 there is shown an audit-credit-interactive system 500. In an exemplary embodiment the audit-credit-interactive system 500 electronics can be located in the VIU 100 enclosure and in general be referred to as a system 500 or VIU 100. In addition, a VIU 100 having an audit-credit-interactive system 500 can be referred to as a MDB controller, a computing platform, a USA TECHNOLOGIES E-PORT, or a USA TECHNOLOGIES G4 E-PORT.

The audit-credit-interactive system 500 provides three major components of functionality. As an audit device the audit-credit-interactive system 500 can audit inventory, sales, operational and other vending machine performance by way of the MDB and DEX interfaces. This gathering and forwarding to a plurality of remote locations of the DEX and or MDB data can be referred to as vending equipment telemetry, or as telemetry data.

When the card reader assembly is added to the system the audit-credit-interactive system 500 provides audit and card processing functionality. The card functional allows cashless vending transactions to occur. Cashless vending transactions are effectuated by allowing various forms of identification (ID), and payment medium to be accepted as or for payment at the vending equipment. Other forms of ID can include, for example and not limitation, smart and magnet cards, radio frequency (RF) ID devices (RFID), user personal identification numbers (PIN) numbers or accounts, or wireless data communication access by way of wireless phone, Bluetooth, 802.11, 802.11B, as well as other suitable protocols or devices. For purposes of disclosure cashless vending refers to non-coin and non-cash transactions.

The audit-credit-interactive system 500 includes numerous mutually exclusive interfaces and control means. In a plurality of customer specifications and where customer cost considerations demand, there may arise a situation where an audit-credit-interactive system 500 maybe manufactured in such a way as to not contain or require the use of certain features, functions, interfaces, and or control means. Accordingly, an audit-credit-interactive system 500 can easily be manufactured to include or exclude a specific combination of features, functions, interfaces, and or control means to produce the desired system performance at a desirable cost to a customer. For example and not limitation, a customer may desire to operate an audit-credit-interactive system 500 without an RFID interface 504. In such a case, an audit-credit-interactive system 500

could be manufactured with the omission of the RFID interface 504. In any combination, the same inclusion or exclusion of features, functions, interfaces and or control means can be applied to other audit-credit-interactive system 500 features, functions, interfaces, and or control means.

5

Interconnected with microcontroller 502 can be an RFID interface 504. The RFID interface 502 can data communicate with wired or wireless devices that are proximate to the RFID interface 504. In an exemplary embodiment these wired and wireless device include, for example and not limitation, touch devices from DALLAS
10 SEMICONDUCTOR, and wireless devices such as the MOBIL SPEED PASS, or other similar or suitable wired or wireless RFID devices. Microcontroller 502 can be any suitable microcontroller, or microprocessor. In an exemplary embodiment a microcontroller 502 can be a ZILOG Z8038220FSC, ZILOG eZ80 type, INTEL,
15 MICROCHIP, MOTOROLA, AMD, UBICOM, or other similar brand or type of microcontroller.

Interconnected with microcontroller 502 can be bill acceptor and coin mechanism interface 506. The bill acceptor and coin mechanism interface 506 emulate industry standard bill acceptor and coin mechanism interfaces. In this regard the audit-credit-
20 interactive system 500 can be interconnected to vending equipment by way of the interface 506. The audit-credit-interactive system 500 mimicking industry standard bill acceptor and coin mechanism electrical control system and signal timing can then operate the vending equipment. Industry standard bill acceptors include serial and pulse style. Serial style bill acceptors utilize INTERRUPT, SEND, ACCEPT ENABLE, and DATA
25 control signal lines. Pulse style bill acceptor and coin mechanism send electrical pulses to an attached control system to indicated the receipt of coin and currency. Serial and pulse style bill acceptors and coin mechanisms can include for example and not limitation MARS, COINCO, CONLUX, or other similar bill acceptors and or coin mechanisms.

Interconnected with microcontroller 502 can be a display interface 508. A display interface 508 can be a liquid crystal display (LCD), a vacuum florescent display, an RS232 connection, and or an electrical interface for driving a display. In an exemplary embodiment display interface 508 can be, for example and not limitation, an RS232 serial connection. Such a serial connection can be utilized to data communicate display data as well as other types of data to a card reader interface board 312.

Interconnected with microcontroller 502 can be a plurality of keypad and button inputs 510.

Interconnected with microcontroller 502 can be memory 512. Memory 512 can be a plurality of different types of memory. In an exemplary embodiment memory 512 can comprise non-volatile random access memory (NOVRAM), flash memory, and serial flash memory. In addition, the NOVRAM can include a timekeeper function for maintaining date and time. NOVRAM can be a DALLAS SEMICONDUCTOR DS1644, DS1646, or DS1647, or other similar or suitable RAM. Flash memory can be an ATMEL or STS brand AT29E010 or other similar style, different size, other brand, or suitable substitute. The serial flash memory can be an ATMEL brand AT45D081, a MICROCHIP 93LC66, or other similar style, different size, other brand, or suitable substitute.

In an exemplary embodiment the timekeeper feature can be effectuated to time and date stamp the transactions as they occur. From the vending equipment's MDB interface CASH VEND transactions, if supported by the VMC, as well as cashless vend transactions can be monitored and recorded. Adding a time and date time stamp to the each transaction as they occur can result in a detailed inventory utilization record showing the date and time the products were vended.

Interconnected with microcontroller 502 can be an office product interface 534. An office product interface 534 can include, for example and not limitation, an optoisolator for counting pulses generated by a fax machines, copy machine, and other office product equipment. In addition, office product interface 534 can include, for
5 example and not limitation, a DTMF decoder for decoding telephone touch-tones and subsequently billing for the use of a telephone line. DTMF decoding can be used in connection with a fax machine to bill for usage based in part on local, long distance, and international dialed locations.

10 Interconnected with microcontroller 502 can be an external peripheral interface 536. The external peripheral interface 536 includes a plurality of configurable input and output line for interfacing to external peripheral devices. External peripheral interface 536 can support serial peripheral interfaces (SPI), serial interfaces such as RS232, RS485, I²C, and other types of peripheral interfaces and communication protocols and
15 standards.

Interconnected with microcontroller 502 can be a network interface 542. A network interface 542 can be an Ethernet, token ring, FIREWIRE, or other similar or suitable type of network interface.

20 A data modem 514 can be interconnected with microcontroller 502. A data modem 514 can effectuate wired and wireless data communications with a plurality of remote locations. Wireless data modems include, for example and not limitation, MOTOROLA, ERICKSON, and NOKIA brands of data modems, as well as SPRINT
25 PCS, CDMA, CDPD, 2G type wireless device, 3G type wireless device, research in motion (RIM) type wireless device, or other similar or suitable brands or types of wireless data modem.

A multi-drop-bus (MDB) interface 518 is interconnected with microcontroller 502. In an exemplary embodiment an MDB interface 518 electrically interconnects with the vending equipment's MDB bus.

5 In accordance with NAMA and other derivative MDB specifications the MDB interface 518 operates in the slave mode being responsive to the vending machine controller (VMC). The VMC typically resides in the vending equipment and operates as the vending equipment's control system. Interconnection with the MDB bus in combination with NAMA and other derivative MDB standard data communications
10 allows the VIU 100 audit-credit-interactive system 500 to reside as a peripheral device to the vending equipment's control system in an auditing and payment device mode of operation.

15 In an exemplary embodiment a VMC can include peripheral device interface support for MDB interface 518, DEX interface 520, bill and coin interface 506, and office products interface 534.

20 In an exemplary embodiment the audit-credit-interactive system 500 is implemented as a cashless reader device on the MDB bus. As a cashless reader the system 500 can audit and transact cashless vending transactions.

A mimic MDB interface 516 can be interconnected with microcontroller 502. Mimic MDB interface 516 unlike MDB interface 518 can operate in both the master and slave modes of operation in accordance with the NAMA and other derivative MDB
25 specifications. The mimic MDB interface 516 can support peripheral devices.

One advantage of this dual mode of operation is that the mimic MDB interface 516 can support proprietary or different versions of MDB protocol and appear to a

peripheral device as a VMC. In this regard peripheral devices that are not compatible with the vending equipment's VMC control system can be interconnected with system 500's mimic MDB bus 516. Through software resident on the system 500 the peripheral device by way of the mimic MDB interface 516 can data communicate with the system 500 and or through the system 500's (with protocol interpolation) MDB interface 518, over the vending equipment's MDB bus to the vending equipment's VMC control system.

A second advantage of the dual mode of operation of the mimic MDB interface 516 is that features supported by a peripheral resultant from the implementation of a derivative MDB specification can be utilized by data communication first to the system 500 by way of the mimic MDB interface 516. If the MDB protocol command is a command supported by the vending equipment's VMC controller the system 500 can then relay the message received from the peripheral device to the VMC control system by way of the system 500's MDB interface 518. In this regard the system 500 essentially acts as a MDB interface gateway sending and receiving non-VMC support portions of a peripheral's implement MDB specifications. In addition, the MDB gateway implemented by the system 500 can allow the peripheral device data communication access to the VMC controller for portions of the peripheral implemented MDB specification supported by the vending equipment's VMC controller.

A data exchange (DEX) interface 520 is interconnected with microcontroller 502. The DEX interface 520 is a serial connection interface for interfacing the system 500 to the VMC control system. In an exemplary embodiment the DEX interface conforms to the EVA-DTS version 4.0 and version 5.0 specifications. In this regard the system 500 can 'DEX' vending equipment and obtain marketing, sales, and operational data as well as other types of data related to the vending equipment operation and performance. In addition, the DEX interface 520 can be utilized to program the VMC control system.

VMC programming can include setting prices and parameters, setting operational data, clearing error codes or messages, and programming the VMC firmware.

A modem 522 can be interconnected with microcontroller 502. Modem 522 can be utilized to data communicate to a plurality of remote locations. Modem 522 can include CERMETEK, XECOM, ZILOG, or other similar brands and types of modems and modem chip sets.

A transceiver 524 can be interconnected with microcontroller 502. In an exemplary embodiment transceiver 524 can effectuate wireless data communication between system 500 and a plurality of remote locations by way of transceiver unit's 200 system 700. A transceiver 524 can be a LINX, or MAX STREAM 430Mhz, 800Mhz, 900MHZ, 2.4Ghz, single frequency or spread spectrum RF module, and or other similar or suitable types of transceiver modules.

Additionally, transceiver 524 can be interconnected with antenna 538. Antenna 538 can be any suitable antenna configured to perform optimally with the selected transceiver and frequency. Antenna 538 can be an ANTENNA FACTOR brand antenna or similar or suitable antenna.

Interconnected with microcontroller 502 can be a card reader interface 526. Card reader interface 526 can support a variety of card reader interfaces and protocols including for example and not limitation bit strobe type of card readers. Bit strobe type of card readers read predefined tracks of data from a magnetic card. To read track data the card reader can incorporate a plurality of DATA lines and DATA CLOCK lines to transfer magnetic card data. Card reader interface 526 can also support serial communication style card readers. Serial communication style card readers can incorporate TRANSMIT, RECEIVE, CLEAR TO SEND, and REQUEST TO SEND

control lines to transfer card data to system 500. Such magnetic card readers can include those manufactured for or by XICO, MAGTEK, NEURON, or other similar or suitable card reader.

5 In addition to accepting magnet cards card reader interface 526 can implement a smart card reader interface. In this regard system 500 by way of card reader interface 526 can read, write, and execute embedded application on a plurality of types and brands of smart cards.

10 An external modem interface 528 can be interconnected with microcontroller 502. In an exemplary embodiment an external modem interface 528 can be an RS232 serial communication interface for interfacing to a plurality data modems, transceivers, and other communication type peripherals. Such data modems, transceivers, and other communication type peripherals can include for example and not limitation
15 MOTOROLA, ERICKSON, NOKIA, SPRINT, AT&T, LINX, MAX STREAM, or other similar or suitable data communication devices.

20 A printer interface 530 can be interconnected with microcontroller 502. A printer interface 530 can be a serial communication style or Centronic style interface. In an exemplary embodiment printer interface 530 can be utilized to print receipts, coupons, and other print data.

25 An interactive interface 532 can be interconnected to microcontroller 502. The interactive interface 532 can be utilized in combination with the interactive interface communication protocol shown in the table below to interconnect the system 500 to a computing platform. The card reader assembly having a card reader interface board 312, which is implementing a card reader user interface system 600, is a computing platform.

In addition, PC based devices, handheld devices, and other microprocessor-based devices are also computing platforms.

In an exemplary embodiment for example and not limitation a computing device
5 can be interfaced to a system 500 by way of the interactive interface 532. In this regard
the two interconnected devices can data communicate by way of an interactive device
interface protocol. This protocol can be implement in and exemplary embodiment as
disclosed in the following table as an example and not limitation where a system 500 can
be referred to as a MDB controller or G4, and host network center 808 can be referred to
10 as USALIVE:

**MDB Controller/G4 E-port/E-port (System 500) Interface
Protocol And Specification**

MDB Controller/G4:

The MDB controller is the microcontroller-based system, which can interfaces to
the vending machines MDB interface and to a computing platform. Such computing
20 platforms include E-port. Certain versions of the E-port may incorporate the MDB
controller and computing platform into a single board solution. In such a case serial
communications between the computing platform and the MDB microcontroller occur
over the devices serial peripheral interface (SPI), serial interface or other similar or
suitable communication interface.

The G4 (system 500) version of E-port can utilize a single microcontroller to
serve as an MDB controller or a semiconductor module as well as a cashless payment
system platform. The G4 device incorporates an RS232 serial interface by which other

computing platforms can interface to and control the functionality of the G4 and associated vending equipment. The G4 version can operate in two modes of operation. In a first mode of operation the G4 provides all the MDB interface control, audit/cashless payment support, and network connectivity. In this mode a computing platform can
5 interact with the G4 in a hybrid role to monitor a string of user text prompts (see DISPLAY PROTOCOL) as well as execute NON-MDB-CONTROL types of commands (see disclosure below).

10 In a second mode of operation the G4 can be configured and serve as an MDB controller (system 500) only. In this mode both the MDB-CONTROL and NON-MDB-CONTROL commands can be executed. While in this mode of operation of the computing platform operates as a master device controlling the operation and process flow of the system. While in this mode the G4 serves as a slave device interfacing to the vending machine and managing the control of the MDB interface. COMMUNICATION
15 INTERFACE details the electrical interconnections required to allow the G4 to data communicate with a computing platform.

Communication Parameters:

20 The MDB controller/G4 communicates to a computing platform by way of serial communications. In this regard a set of commands issued from the computing platform implement a level of control via the MDB controller/G4 and the MDB/ICP protocol to transact a cashless transaction and obtain DEX data information.

25 Serial communications between the computing platform and the MDB controller/G4 are set at 9600 baud, 8 data bits, No Parity, and 2 Stop bits. Required serial port communications lines include transmit (Txd), Receive (Rxd) and Ground (Gnd).

MDB CONTROLLER/G4 COMMAND PROTOCOL

5

Protocol Exchange:

The “master” computing platform can initiate any ‘@’ or ‘#’ command listed in the command disclosure below. In response to a complete command the MDB controller/G4 will process and return the result string. The result string shall start with a start character (STX) hex \$02, and conclude with an ETX character hex \$03. A LRC check byte will immediately follow the ETX character.

STX	hex \$02
ETX	hex \$03
<esc>	ESCAPE character hex \$1B
LRC	all bytes XORed excluding the STX character and including the ETX character.

Protocol Exchange Characters

15

It is recommended that the ‘@’ commands be executed by inserting a leading space prior to the ‘@’. For example sending ‘ @<esc>H’ instead of ‘@<esc>H’ the differencing being a leading space. The leading space will decrease command communication errors by allowing the MDB Controller/G4 to sync on the leading space.

20

MDB-CONTROL-COMMANDS

Command Description:

@<esc>T – REQUEST FOR CARD READER DATA.

If no card reader data is available then the result string will return:

5

STX+[CARD-NOCARDDATA]+ETX+LRC

Else the result string will return:

10

STX+[CARD-][UPTO 37 BYTES MAX OF CARD DATA]+ETX+LRC

Example of valid card data:

15

STX+[CARD-41324132413243132=9182738937463764372]+ETX+LRC

@<esc>Z – CLEAR CREDIT CARD DATA. The credit card buffer will be cleared and The result NOCARDDATA will be inserted in the buffer and returned in response to the @<esc>T command. The result string will return.

20

STX+[OK-Z]+ETX+LRC

@<esc>V – REQUEST FOR MDB TRANSACTION STRING DATA. The result string will return:

25

STX+[S]+[xxxxxx Field #1 6 bytes]+[xxxxxx Field #2 6 bytes]+[xxxx Field #3 4 bytes]+[F]+ETX+LRC

Where ‘xxx...’ denotes fixed length fields. These fields should be right justified and have leading zeros added to fix the length of each field. For example \$1.50 should be represented as 000150.

5 The ‘S’ field is the state current MDB state. Valid states include:

State	Description
I	Inactive
D	Disable
E	Enabled
S	In Session
V	Vend

Valid Vending States

10 Field #1 is the MAX VEND PRICE as reported by the vending machine controller (VMC) during the MDB initialization process. This is a 6-byte field.

15 Field #2 is the SALE PRICE. The SALE PRICE is determined in the MDB protocol for the VEND – Request Command (See. NAMA Multi Drop Bus (MDB)/Internal Protocol Version 1.0, and 2.0 specifications).

20 Field #3 is the COLUMN information. The COLUMN information is determined in the MDB protocol for the VEND – Request Command (See. NAMA Multi Drop Bus (MDB)/Internal Protocol Version 1.0, and 2.0 specifications).

20 The ‘F’ field is the MDB transaction condition flag. Valid flag states include:

State	Description
C	Clear
\$	Currency vend has occurred
P	Vend pending
V	Cashless vend has occurred
F	Vend fail

Valid Flag States

The 'C' flag is set when the MDB transaction string is cleared. The '\$' flag is set when a VEND CASH MDB transaction occurs. The 'P' flag is set when a VEND – APPROVED
5 MDB command is issued and remains valid until the VEND SUCCESSFUL or VEND FAIL MDB command is issued. The 'F' flag is set when a VEND FAILS.

Examples of MDB transaction strings:

10 STX+[E0001500000000000C]+ETX+LRC -> Enabled, MAX Vend price \$1.50,
transaction string in cleared state

STX+[S0001500000000000C]+ETX+LRC -> In session, MAX Vend price \$1.50,
transaction string in cleared state

15 STX+[V0001500001000002P]+ETX+LRC -> Vend state, MAX Vend price \$1.50, sale
price \$1.00, vend from column 2, vend pending

20 STX+[E0001500001000002V]+ETX+LRC -> Enable state, MAX Vend price \$1.50,
sale price \$1.00, vend from column 2, vend complete

STX+[E0001500001250003\$]+ETX+LRC -> Enable state, MAX Vend price \$1.50,
sale price \$1.25, vend from column 3, cash vend

IMPORTANT NOTE: The MDB microcontroller/G4 MDB interface will continuously
manage the changes to the MDB transaction string. For example as the MDB state
changes, the MDB state field will automatically be updated. There are however two
scenarios that require the execution of the @<esc>C – CLEAR MDB TRANSACTION
STRING DATA command. These two scenarios include when a currency vend has
occurred the 'F' field has been set to '\$', and when a cashless vend has occurred and the
'F' field has been set to 'V'. In both these cases the @<esc>C command will have to
executed to clear the MDB TRANSACTION STRING before a new cash transaction can
be tracked or a new cashless vending session can be started.

If the G4 is used in the VEND ACTIVE 'ON' mode the above does not apply in that the
G4 will clear the MDB TRANSACTION string as appropriate. If the G4 is used in the
G4 VEND ACTIVE 'OFF' the above will apply.

@<esc>C – CLEAR MDB TRANSACTION STRING DATA. The MDB controller/G4
will clear the SALE PRICE field, COLUMN information field, and the transaction
condition flag is set to 'C'. The result string will return:

STX+[OK-C]+ETX+LRC

@<esc>H – HYBRID COMMAND FOR SEND CARD DATA AND MDB STRING.

The MDB controller/G4 will send both the card reader data (see @<esc>T above)
followed by the MDB string (see @<esc>V). The result string will return:

STX+[@<esc>T response]+ETX_LRC+STX+[@<esc>V RESPONSE]+ETX+LRC

@<esc>S – BEGIN A SESSION COMMAND. The MDB controller/G4 will begin an MDB session (see NAMA MDB specification V1.0, V2.0 for BEGIN SESSION command). The result string will return:

STX+[OK-S]+ETX+LRC

The G4 must have the MDB state set to 'E' for ENABLED in order to start a session. If a session cannot be started the result string will return:

STX+[UNABLE-S]+ETX+LRC

@<esc>X – END A SESSION COMMAND. The MDB controller/G4 will END an MDB session (see NAMA MDB specification V1.0, V2.0 for SESSION CANCEL command). The result string will return:

STX+[OK-X]+ETX+LRC

@<esc>F – SET MDB CONTROLLER STATE TO INACTIVE. The MDB controller/G4 will set the MDB state to Inactive. The result sting will return:

STX+[OK-F]+ETX+LRC

@<esc>D – SET MDB CONTROLLER STATE TO DISABLE. The MDB controller/G4 will set the MDB state to Disable. The result sting will return:

STX+[OK-D]+ETX+LRC

@<esc>E – SET MDB CONTROLLER STATE TO ENABLE. The MDB controller/G4 will set the MDB state to Enable. The result sting will return:

5

STX+[OK-E]+ETX+LRC

@<esc>K – PERFORM A HARDWARE MDB CONTROLLER RESET. The MDB controller/G4 will return the result string and then go through a hardware reset. The result sting will return:

10

STX+[OK-K]+ETX+LRC

@<esc>I – TOGGLE INTERRUPT MODE. The MDB controller/G4 will return the result string below toggling between 'ON' and 'OFF' of the interrupt mode.

15

STX+[ON-I]+ETX+LRC -> When toggling into the interrupt mode

STX+[OFF-I]+ETX+LRC -> When toggling out of the interrupt mode

20

@<esc>I – turns mode 'ON'

STX+[ON-I]+ETX+LRC -> When toggling into the interrupt mode

@<esc>i – turns mode 'OFF'

STX+[OFF-I]+ETX+LRC -> When toggling out of the interrupt mode

25

While in the interrupt mode the MDB controller/G4 will send the result string for the @<esc>T and the @<esc>V commands shown above each time the respective data fields change.

For example, while in the interrupt mode the MDB controller/G4 will send the @<esc>T result string on the successful read of a magnetic card.

- 5 In addition, while in the interrupt mode the MDB controller/G4 will send the @<esc>V result string each time any field in the MDB transaction string changes.

Default: The default condition on microcontroller reset is 'OFF'.

- 10 @<esc>1 – TOGGLE MDB CODE CAPTURE MODE. The MDB controller/G4 will return the result string below toggling between 'ON' and 'OFF' of the MDB CODE CAPTURE mode. This command is for diagnostic purposes only and should not be used during normal G4 operation. The intended purpose for this command is to diagnosis MDB related transaction issues during development and or testing.

- 15 STX+[ON-I]+ETX+LRC -> When toggling into the MDB code capture mode.

STX+[OFF-I]+ETX+LRC -> When toggling out of the MDB code capture mode

- 20 When the MDB code capture mode is switched to the 'ON' mode the following sequence of events begins:

- 25 The NOVRAM memory dedicated to the storage of vending transaction is cleared. All data (transactions) currently being stored will be erased to make room for the MDB bus codes.

The G4 will begin record both the received MDB codes from the vending machine controller (VMC) and the sent MDB codes from the G4. There is RAM room for approximately 15 seconds of recording time.

- 5 When the MDB code capture mode is switched to the 'OFF' mode the G4 will stop recording the MDB bus codes. A buffer dump of the MDB codes exchanged between the G4 and the VMC can be viewed by executing @<esc>2 the MDB CAPTURED CODE BUFFER DUMP command.

- 10 Two important notes:

When you are ready to return the G4 system to the normal operation mode you should 1) insure that the MDB CODE CAPTURE mode is 'OFF' and 2) Execute the @<esc>J CLEAR MAIN MEMORY command to clear and reset the G4 main memory. The
15 CLEAR MAIN MEMORY command is important in that the MDB codes captured are stored in the NOVRAM area and may interfere with the G4 normal record management procedures.

- 20 When the MDB capture mode is switched to 'ON' the G4 will stay in this state until either 1) the buffer area for MDB codes is filled (about 15 seconds) or 2) the MDB capture mode is switched to 'OFF'. Even if the G4 is powered 'OFF' or the @<esc> K HARDWARE RESET command is issued the MDB capture mode state will not change. The reason for this is to allow the MDB capture mode to be turned 'ON' and remain 'ON' capturing MDB transaction codes between the vending machine and the G4 while
25 the vending machine and or G4 go through a power up or reset procedure.

If the G4 is in a vending transaction the TOGGLE MDB CODE CAPTURE MODE command cannot be executed to turn 'ON' the MDB capture feature. If the TOGGLE

MDB CODE CAPTURE MODE command is executed during a vending session the MDB capture mode will be turned 'OFF' and result string will return:

STX+[OFF-1]+ETX+LRC

5

Default: The default condition on microcontroller reset is 'OFF'.

@<esc>2 – MDB CAPTURE MODE BUFFER DUMP. The MDB controller/G4 will return the result string below dumping the MDB codes passed between the G4 and the vending machine controller (VMC). The output will be formatted to indicate which codes were transmitted by the VMC and which codes were transmitted by the G4. This command is for diagnostic purposes only and should not be used during normal G4 operation. The intended purpose for this command is to diagnosis MDB related transaction issues during development and or testing.

10

15

STX+[MDB]+ -> Header

[VMC-]+VMC transmitted data -> Data transmitted by the VMC

[G4 -]+G4 transmitted data -> Data transmitted by the G4

20

....

ETX+LRC

Command Description:

25 @<esc>\$ – SIMULATE CASH VEND TRANSACTION. The G4 will simulate a CASH VEND transaction (see MDB spec V1.0 for CASH VEND command). The result sting will return:

STX+[OK-]+ETX+LRC

To simulate the CASH VEND the MDB transaction string will be set to the following:

5 STX+[E0005000001250001\$]+ETX+LRC

If the G4 is in a vending transaction a SIMULATE CASH VEND transaction cannot be executed. If a SIMULATE CASH VEND transaction cannot be executed the result string will return:

10 STX+[UNABLE-]+ETX+LRC

@<esc># – SIMULATE CASHLESS VEND TRANSACTION. The G4 will simulate a CURRENCY VEND transaction (see NAMA MDB spec V1.0 and V2.0 for VEND REQUEST and VEND APPROVED commands). The result sting will return:

15 STX+[OK-#]+ETX+LRC

20 To simulate the CASHLESS VEND the MDB transaction string will be set to the following:

STX+[E0005000001250001V]+ETX+LRC

25 If the G4 is in not in a vending transaction a SIMULATE CASHLESS VEND transaction cannot be executed. If a SIMULATE CASHLESS VEND transaction cannot be executed the result string will return:

STX+[UNABLE-#]+ETX+LRC

@<esc>M – TOGGLE MODEM COMMUNICATION ACCESS. The G4 will switch the serial communication ports being utilized by the computing platform to the MDB controller/G4 communication port. In this regard the computing platform can utilize the communication port (modem and or wireless) of the MDB controller/G4. The result sting will return:

STX+[ON-M]+ETX+LRC -> When toggling into the communication mode – allowing the computing platform to use the MDB controller/G4 communication port. A communication hardware reset will also be invoked in the G4 to prepare the communication device to receive data.

STX+[OFF-M]+ETX+LRC -> When toggling out of the communication mode

IMPORTANT NOTE: The communication parameters between the G4 are outlined above as 9600, no parity, 8 data bits, and 2 stop bits. Upon executing the @<esc>M command 'ON' the G4 switches direct access to the communication device. If for example, a 2400 baud modem is being used the device issuing the @<esc>M command will have to first change its baud rate to 2400 before the G4 modem can respond to the requests. Furthermore, upon the conclusion of a communication session before the @<esc>M command can be issued and interrupted by the G4 to switch the communications 'OFF' the baud rate of the device issuing the @<esc>M command should change its baud rate back to 9600 N, 8, 2.

Default: The default condition on microcontroller reset is 'OFF'

@<esc>Q – SEND CURRENT TRANSACTION RECORD. The G4 will return the current transaction record. The current transaction record is a fixed length record. The parsed fields are a list below. The result sting will return:

5 STX+[RECORD NUMBER-TRANSACTION RECORD]+ETX+LRC

If the G4 is not in a vending transaction a SEND CURRENT TRANSACTION RECORD transaction cannot be executed. If a SEND CURRENT TRANSACTION RECORD transaction cannot be executed the result string will return:

10

STX+[UNABLE-Q]+ETX+LRC

Where the parsed [record number-transaction record] fields are as follows:

RECORD TYPE	BYTES	DESCRIPTION
RECORD NUMBER	4 bytes	Current transaction record number
SEPARATOR	1 byte	Field separator ‘-‘
CARD DATA/ID DATA	37 bytes	Card data or Dial-A-Vend data
MERCHANT ID REFERENCE	1 byte	Merchant ID Prefix (G4 specific typically set to ‘1’)
SALE AMOUNT	5 bytes	Transaction sale amount
APPROVAL CODE	8 bytes	Transaction approval code (typically starts with AP)

CAPTURE ID FLAG	1 byte	Transaction Capture Flag/ Transaction ID 0=DO NOT CAPTURE TRANSACTION 1=CREDIT CARD TRANSACTION 2=SETTLEMENT DATA 3=ERROR RECORD 4=SETTLED CREDIT CARD TRANSACTION 5=PRIVATE SYSTEM TRANSACTIONS 6=NOT USED 7=EMAIL TRANSACTION
START TIME	8 bytes	Transaction Start Date and Time (MMDDHHMM)
COUNT 1	4 bytes	Event counter #1 i.e. copy or print count (XXXX)
STOP TIME	8 bytes	Transaction Stop Date and Time (MMDDHHMM)
COUNT 2	4 bytes	Event counter #2 i.e. copy or print count (XXXX)
INVENTORY TOTAL	2 bytes	Total vended inventory count
ITEM COLUMN 1	2 bytes	Vended item #1 column data
ITEM COLUMN 2	2 bytes	Vended item #2 column data
ITEM COLUMN 3	2 bytes	Vended item #3 column data
ITEM COLUMN 4	2 bytes	Vended item #4 column data
ITEM COLUMN 5	2 bytes	Vended item #5 column data
ITEM COLUMN 6	2 bytes	Vended item #6 column data
ITEM COLUMN 7	2 bytes	Vended item #7 column data
ITEM COLUMN 8	2 bytes	Vended item #8 column data

ITEM COLUMN 9	2 bytes	Vended item #9 column data
ITEM COLUMN 10	2 bytes	Vended item #10 column data
SPARE DATA	2 bytes	Not Implemented
LRC CHECK BYTE	1 byte	LRC check byte

Transaction Record Format

@<esc>W – SEND CURRENT TRANSACTION RECORD. The MDB controller/G4 will return all the transaction records beginning with 0000. The G4 will return the message ‘DONE’ when complete. The transaction records are a fixed length records and follow the format shown above in the @<esc>Q command. The result sting will return:

STX+[0000-TRANSACTION RECORD]+ETX+LRC
...
...
...
STX+[xxxx-TRANSACTION RECORD]+ETX+LRC

DONE

Where ‘0000’ is the first transaction record and ‘xxxx’ is the last transaction record.

If the G4 is in a vending transaction a SEND CURRENT TRANSACTION RECORD transaction cannot be executed. If a SEND CURRENT TRANSACTION RECORD transaction cannot be executed the result string will return:

STX+[UNABLE-W]+ETX+LRC

@<esc>R – TOGGLE VERBOSE TEXT PROMPTS ON/OFF. The G4 will switch between providing a stream of text prompts (see DISPLAY PROTOCOL) when the VERBOSE mode is turned 'ON' and disabling the transmission of the text prompts when the VERBOSE mode is 'OFF'. The result sting will return:

5

STX+[ON-R]+ETX+LRC -> When toggling into the VERBOSE mode.

STX+[OFF-R]+ETX+LRC -> When toggling out of the VERBOSE mode

10

@<esc>R – turns mode 'ON'

STX+[ON-R]+ETX+LRC -> When toggling into the VERBOSE mode.

@<esc>r – turns mode 'OFF'

STX+[OFF-R]+ETX+LRC -> When toggling out of the VERBOSE mode

15

Default: The default condition on microcontroller reset is 'ON'

20

@<esc>Y – TOGGLE G4 VEND ACTIVE MODE ON/OFF. The G4 can operate in two modes of operation. In the VEND ACTIVE 'ON' mode of operation the G4 provides all the MDB interface control, audit/cashless payment support, and network connectivity. In this mode a computing platform can interact with the G4 in a hybrid role to monitor a string of user text prompts (see DISPLAY PROTOCOL) as well as execute the NON-MDB-CONTROL and some MDB-CONTROL commands.

25

In the VEND ACTIVE 'OFF' mode of operation the G4 can be configured and serve as an MDB controller only. In this mode both the MDB-CONTROL and NON-MDB-CONTROL commands can be executed. While in this mode of operation the computing platform operates as a master device controlling the operation and process flow of the

system, and the G4 serves as a slave device interfacing to the vending machine and managing the control of the MDB interface. The result sting will return:

STX+[ON-R]+ETX+LRC -> When toggling into the VEND ACTIVE mode.

5

STX+[OFF-R]+ETX+LRC -> When toggling out of the VEND ACTIVE mode

@<esc>Y – turns mode ‘ON’

STX+[ON-R]+ETX+LRC -> When toggling into the VEND ACTIVE mode.

10

@<esc>y – turns mode ‘OFF’

STX+[OFF-R]+ETX+LRC -> When toggling out of the VEND ACTIVE mode

Default: The default condition on microcontroller reset is ‘ON’

15

@<esc>U – RETURN TO DEFAULT CONDITIONS. The G4 will return all settings to the power on/system reset default condition. The result sting will return:

STX+[OK-U]+ETX+LRC

20

Reset Default Conditions Include:

INTERRUPT MODE = ‘OFF’

VERBOSE MODE = ‘ON’

25

VEND ACTIVE MODE = ‘ON’

@<esc>P – RETURN G4 TIME AND DATE STAMP. The G4 will return the current time and date. The time and date are set by the USALIVE (host network center 808) server each time the G4 communicates with the network servers. The result sting will return:

30

STX+[TIME-HHMMSS-MMDDYY]+ETX+LRC

Where 'HHMMSS' is the current hour, minute, and seconds, and 'MMDDYY' is the
5 current month, day, and year.

@<esc>G – PRINT A RECEIPT FOR CURRENT TRANSACTION. The G4 will
internally call the print receipt routine to print a receipt for the current transaction. The
result sting will return:

10 STX+[OK-G]+ETX+LRC

@<esc>J – CLEAR MAIN MEMORY TRANSACTIONS. The G4 main memory will
be cleared. The result sting will return:

15 STX+[OK-J]+ETX+LRC

@<esc>N – FIND A BLANK RECORD. The G4 finds and sets active the next available
20 blank transaction record. The result sting will return:

STX+[OK-N]+ETX+LRC

The G4 must have the MDB state set to 'E' for ENABLED in order to find a blank
25 record. A new record cannot be started while in a vending transaction. If a FIND BLANK
RECORD command cannot execute the result string will return:

STX+[UNABLE-N]+ETX+LRC

@<esc>**B** – START A VEND SESSION. Provided the G4 VEND ACTIVE ‘ON’ mode is set, the G4 will start a vend session. The sequence to starting a vend session include:

5

G4 finds the next available blank transaction record

G4 loads the default data into the transaction record

G4 loads as the CARD DATA/ID DATA -> ‘G4-VEND’

G4 issues the BEGIN SESSION command to the MDB interface.

10

The result sting will return:

STX+[OK-B]+ETX+LRC

15

The G4 must have the MDB state set to ‘E’ for ENABLED in order to start a session. If a session cannot be started the result string will return:

STX+[UNABLE-B]+ETX+LRC

20

@<esc>**A**+STX+[ID DATA Up to 30 bytes]+ETX+LRC – START A DIAL-A-VEND SESSION. Provided the G4 VEND ACTIVE ‘ON’ mode is set, the G4 will start a vend session. The sequence to starting a vend session include:

25

G4 finds the next available blank transaction record

G4 loads the default data into the transaction record

G4 loads as the CARD DATA/ID DATA the ‘[DV-]+[ID DATA Up to 30 bytes]’ sent as part of the command.

G4 issues the BEGIN SESSION command to the MDB interface.

The result sting will return:

STX+[OK-A]+ETX+LRC

5

The G4 must have the MDB state set to 'E' for ENABLED in order to start a dial-a-vend vending transaction. A new vending transaction cannot be started while in a vending transaction. If a dial-a-vend command cannot execute the result string will return:

STX+[UNABLE-A]+ETX+LRC

10

If the LRC character does not match, or the correct ETX+LRC combination does not occur at all or in a timely fashion the result string will return:

STX+[NAK-A]+ETX+LRC

15

@<esc>L – REQUEST USALIVE SETTING DATA. The G4 will return a string of USALIVE setting data. USALIVE setting data can be referred to as system 500 terminal management data. USALIVE can be referred to as the host network center 808. The USALIVE setting data includes terminal configuration, setting, and parameter data maintained on the USALIVE network and passed to the terminal each time the terminal communicates to the USALIVE network. Changes to the data are managed on the server. The result sting will return:

20

STX+[START-]+[USALIVE SETTING DATA]+[-END]+ETX+LRC

25

@<esc>3 – TOGGLE DEX CODE CAPTURE MODE (FULL FORMAT). The DEX controller/G4 will return the result string below toggling between 'ON' and 'OFF' of the

DEX CODE CAPTURE mode. This command is for diagnostic purposes only and should not be used during normal G4 operation. The intended purpose for this command is to diagnosis DEX related transaction issues during development and or testing. The @<esc>3 command obtains DEX data in a free format capturing the handshake and protocol exchanges (ACK, NAK, DLE, etc.) in addition to the DEX data. At the conclusion of the DEX data transfer the DEX CAPTURE MODE is automatically toggled 'OFF'. In most cases there will be no need to execute a second @<esc>3 command to toggle the DEX mode 'OFF'.

10 STX+[ON-I]+ETX+LRC -> When toggling into the DEX code capture mode

STX+[OFF-I]+ETX+LRC -> When toggling out of the DEX code capture mode

15 When the DEX code capture mode is switched to the 'ON' mode the following sequence of events begins:

The NOVRAM memory dedicated to the storage of DEX data is cleared.

20 The G4 will begin recording both the received DEX codes from the vending machine controller (VMC) and the sent DEX codes from the G4. There is RAM room for approximately 6K bytes of recorded DEX data.

25 When the DEX code capture mode is switched to the 'OFF' mode or automatically switches to the 'OFF' mode at the end of the DEX transfer the G4 will stop recording the DEX bus codes. A buffer dump of the DEX codes exchanged between the G4 and the VMC can be viewed by executing the @<esc>5 the DEX CAPTURED CODE BUFFER DUMP command.

Default: The default condition on microcontroller reset is 'OFF'.

@<esc>4 – TOGGLE DEX CODE CAPTURE MODE (PARSED FORMAT). The DEX controller/G4 will return the result string below toggling between 'ON' and 'OFF' of the DEX CODE CAPTURE mode. This command is for diagnostic purposes only and should not be used during normal G4 operation. The intended purpose for this command is to diagnosis DEX related transaction issues during development and or testing. The @<esc>4 command obtains DEX data in a parsed, pure format (free from all handshake and protocol exchanges (ACK, NAK, DLE, etc.)). At the conclusion of the DEX data transfer the DEX CAPTURE MODE is automatically toggled 'OFF'. In most cases there will be no need to execute a second @<esc>4 command to toggle the DEX modem 'OFF'.

STX+[ON-I]+ETX+LRC -> When toggling into the DEX code capture mode

STX+[OFF-I]+ETX+LRC -> When toggling out of the DEX code capture mode

When the DEX code capture mode is switched to the 'ON' mode the following sequence of events begins:

The NOVRAM memory dedicated to the storage of DEX data is cleared.

The G4 will begin recording both the received DEX codes from the vending machine controller (VMC) and the sent DEX codes from the G4. There is RAM room for approximately 6K bytes of recorded DEX data.

When the DEX code capture mode is switched to the 'OFF' mode or automatically switches to the 'OFF' mode at the end of the DEX transfer the G4 will stop recording the

DEX bus codes. A buffer dump of the DEX codes exchanged between the G4 and the VMC can be viewed by executing the @<esc>5 the DEX CAPTURED CODE BUFFER DUMP command.

5 Default: The default condition on microcontroller reset is ‘OFF’.

@<esc>5 – DEX CAPTURE MODE BUFFER DUMP. The DEX controller/G4 will return the result string below dumping the DEX codes passed between the G4 and the vending machine controller (VMC). The output will be formatted to indicate the codes transmitted by the VMC and the G4. This command is for diagnostic purposes only and should not be used during normal G4 operation. The intended purpose for this command is to diagnosis DEX related transaction issues during development and or testing.

STX+[DEX]+	-> Header
[VMC-]+VMC transmitted data	-> Data transmitted by the VMC
[G4 -]+G4 transmitted data	-> Data transmitted by the G4
....	
ETX+LRC	

If DEX data is obtained with the @<esc>3 command the DEX data will be parsed to remove all handshake data and VMC/G4 protocol passing. The DEX data will be pure and presented in ASCII format. If the DEX data is obtained with the @<esc>4 command the DEX data will include all the handshaking data and VMC/G4 protocol passes (ACK, NAK, DLE, etc.). The DEX data will be presented in ASCII HEX format.

#<esc>C – ENTER SERVICE MODE ROUTINE – The G4 will return the following result string and then enter the service mode.

STX+[OK-C]+ETX+LRC

5

#<esc>D – SYSTEM INITIALIZATION COMMAND – The G4 will return the following result string and then perform a system initialization sequence.

STX+[OK-D]+ETX+LRC

10

The system initialize sequence will clear memory and reload initial condition registers. The USALIVE default phone number will be loaded into memory and the G4 will be placed in the CALL HOME mode. Before correct terminal operation can be restored the G4 will require communication with the USALIVE servers.

15

#<esc>E – DISPLAY SERIAL NUMBER AND FIRMWARE VERSION – The G4 will return the following result string showing the G4 serial number and firmware version number.

20

STX+[OK-E]+ETX+LRC

Followed by the G4 serial number and firmware version number.

#<esc>F – SET CALL HOME FLAG TRUE – INITIATE CALL HOME – The G4

25

CALL HOME flag will be set directing the terminal to begin a timer. The timer is a USALIVE setting the delays the call in process after the CALL HOME flag is set. The result code returned will be as follows:

STX+[OK-F]+ETX+LRC

The G4 will then in time place a call to the USALIVE servers.

- 5 #<esc>G – RETURN CURRENT STATE OF CALL HOME FLAG – The G4 will return the following result code indicating the current state of the CALL HOME flag. The states can be either TRUE or FALSE. TRUE indicating the G4 is preparing to place a call to the USALIVE servers.

10 STX+[TRUE-F]+ETX+LRC
or ...
STX+[FALSE-F]+ETX+LRC

- 15 #<esc>H – CLEAR THE CALL HOME FLAG – SET TO FALSE – The G4 will reset the CALL HOME flag to FALSE. The following result code will be returned.

STX+[OK-H]+ETX+LRC

- 20 If the G4 terminal is experiencing a situation that under normal circumstance would trigger the G4 terminal to CALL HOME to the USALIVE servers, such as a DEX alarm condition is detected, or the G4 has a full memory of transaction the CALL HOME flag will automatically be set back to TRUE.

- 25 #<esc>I – RETURNS THE CURRENT SERVICE STATE OF THE TERMINAL – The G4 will return the following result codes indicating the terminal is either IN or OUT of service at the present moment.

STX+[IN-I]+ETX+LRC

or ...

STX+[OUT-I]+ETX+LRC

- 5 **#<esc>J** – TOGGLES THE CURRENT SERVICE STATE (IN/OUT) – The G4 will toggle the current service state from either IN to OUT or from OUT to IN. The result string returned will be as follows.

STX+[IN-J]+ETX+LRC

or ...

STX+[OUT-J]+ETX+LRC

10

15

- #<esc>K** – SEND CURRENT LOCAL AUTHORIZATION RECORD – The G4 will return the result string that includes the record number, last six digits of each card, and the 'A' or 'D' suffix indicating APPROVAL or DECLINED record data as follows:

STX+[xxxx-LAST SIX DIGITS OF CARD NUMBER-A or D]+ETX+LRC

Where 'xxxx' is the current record number.

20

- #<esc>L** – SEND COMPLETE LOCAL AUTHORIZATION DATABASE - The G4 will return the result string that includes the record number, last six digits of each card, and the 'A' suffix indicating APPROVAL record data as follows:

25

STX+[xxxx-LAST SIX DIGITS OF CARD NUMBER-A or D]+ETX+LRC

...

...

...

STX+[yyyy-LAST SIX DIGITS OF CARD NUMBER-A or D]+ETX+LRC

DONE

5

Where 'xxxx' is the first record number and 'yyyy' is the last record number.

#<esc>M – CLEAR DECLINED CARD PORTION OF LOCAL AUTH DATABASE –

The G4 terminal will clear the DECLINED cards in the LOCAL AUTHORIZATION
10 database and return the following result code:

STX+[OK-M]+ETX+LRC

#<esc>N – CLEAR APPROVAL CARD PORTION OF LOCAL AUTH DATABASE –

The G4 terminal will clear the APPROVAL cards in the LOCAL AUTHORIZATION
15 database and return the following result code:

STX+[OK-N]+ETX+LRC

20 #<esc>O – INITIATE A DEX QUERY MODE INQUIRY – The G4 will issue the DEX
QUERY MODE string to the attached VMC. See the EVA-DTS DEX protocol standard
for detail on the DEX QUERY MODE of operation. The G4 will react to the returned
DEX QUERY MODE result from the VMC and issue the following result string:

25

STX+[OK-O]+ETX+LRC

AAA - END SESSION AND PRINT RECEIPT. A session started when the G4 is in the
VEND ACTIVE 'ON' mode is terminated and a receipt optionally printed by send a

BBB – BUTTON 2 PRESS. While in the service mode send a string of ‘BBB...’ has the same effect as inserting a card in the card reader to advance a menu selection or setting. The correct use of this command should be to send a string of at least three ‘B’ characters.

Text Display Overview:

To simplify the interface and functionality requirements of the computing platform the text prompts from the G4 can be captured and displayed on the computing platform display. Doing so alleviates the need for the computing platform to ascertain and or determine what message should be displayed to the user. In addition, allowing the G4 to manage the vending transaction, MDB interface, and text prompts removes the need for the computing platform to get involved in the vending transaction.

The text format display protocol below illustrates how the G4 sends text prompts. The selection of the control characters is consistent with the operating functionality of many text LCD displays.

Communication Interface:

Shown in Figure 1A and 1B are external views of the G4. The display port/interactive
5 interface port provides the interconnectivity to external devices and computing platforms
for the purpose of control as outlined above and for display control as outlined in this
section and its subsections.

The display port/interactive interface is a DB-9 pin male connector. As shown below the
10 port is a hybrid serial port with power tap for low current external devices.

PIN #	PIN ID	DESCRIPTION
Pin 1	Not Used	
Pin 2	Rxd	Receive Input To G4
Pin 3	Txd	Transmit Output From G4
Pin 4	Not Used	
Pin 5	GND	
Pin 6	+5VDC	Power 300ma Max.
Pin 7	CTS	Clear To Send Input To G4
Pin 8	RTS	Request To Send Output From G4
Pin 9	Optional +Vprinter	With Additional Power Supply

Connector Pin Out

The communication pins Rxd, Txd, CTS, and RTS conform to RS232 standards. A
15 minimum of Rxd, Txd, and GND are required to implement serial communication

between the G4 and a computing platform. The RTS and CTS lines only come into play from a flow control prospective when receipt data is being sent from the G4. CTS and RTS are implemented in such a way as to allow a receipt printer that has little to no printer buffer to control the flow of data. CTS and RTS have no other purpose in non-print data communications and can be ignored or left unimplemented.

Display and Control Codes:

The G4 will send a series of display and control codes to indicate when screen initializing and format could occur. In interpreting the display and control codes the computing device will know when to blank the display area and as appropriate when and where to locate cursor positions.

The display and control codes are sent from the G4 as a string of hex characters. The table of display control codes is as follows:

DISPLAY CONTROL CODES	DESCRIPTION
\$FE+\$FE+\$FE	Beep Beeper
\$FD+\$FD+\$FD	Indicates print data is to follow (start print data)
\$FC+\$FC+\$FC	Indicates print data is concluded (end print data)
\$FB+\$FB+\$FB	Indicates a transaction is active – used to start a LED or set a status indicator to reflect a transaction is active. This command can be used to indicate to a user to press an 'END' button to end vend session.

\$FA+\$FA+\$FA	Indicates a transaction is NOT active. If a LED or status indicator is 'ON' resultant from the above \$FB command this command should be interrupted as negating the \$FB command.
\$F9+\$F9+\$F9	Clear display area. If a text LCD is being used this command could indicate when a display initialization process could be started. Such a process has the effect of initializing the LCD and clearing the display area.
\$F7+\$F7+\$F7	Indicates a transaction is ready to be started. Such is the case when the MDB interface indicates the G4 is ENABLED to conduct a vend, and the G4 is ready to start a transaction. This command can be used to indicate to a user by way of LED or status indicator that the G4 is ready to accept command and or magnetic card to start a vending transaction.
\$F6+\$F6+\$F6	Indicates the G4 is not ready to start a vending transaction. If a LED or status indicator is 'ON' resultant from the above \$F7 command this command should be interrupted as negating the \$F7 command.

Table of Display Control Codes

Text Prompt Format:

- 5 The G4 supplies text prompts in a fixed format. The format supports two lines of text each line being a maximum of 16 characters. The format includes a leading character, which indicates the line (line 1 or 2) the text should be displayed on, up to 16 characters of text to be displayed, and a trailing character to indicate the end of the text message. When possible the text message should be formatted to contain 16 bytes. Leading spaces

and trailing spaces can be used to position the text message and format the text string to 16 bytes.

The leading character conforms to the format supported by many text LCD display

5 modules. The leading character will be a hex \$80 to indicate the text message should be displayed on line 1 of the display area. A hex \$C0 will indicate the text message should be displayed on line 2 of the display area.

10 The trailing character will be a hex \$F8. The trailing character indicates the end of the text message.

Text message format:

15 Lead Character = \$80 – Line 1
 \$C0 – Line 2
 Trailing Character = \$F8

[Lead Character]+[Up to 16 bytes of text message]+[Trailing Character]

20 Example: \$80+[Swipe A Valid]+\$F8
 \$C0+[Credit Card]+\$F8

The above will display ‘ Swipe a Valid ’ on line 1 of the display area, and
‘ Credit Card ’ on line 2 of the display area.

25

Cursor Display Codes

The G4 uses a series of display codes to locate the position of the cursor. There are a maximum of 32 cursor positions – two rows of 16 characters. In addition there are cursor display codes to turn ‘ON’ a flashing cursor, turn ‘ON’ an underline cursor (show cursor), and to turn ‘OFF’ the cursor (hide cursor). The codes are similar to those used for typical text LCD displays.

To locate the cursor in the display area the table below illustrates the hex code and corresponding cursor location.

	Column 1															Column 16
Row 1	\$80	\$81	\$82	\$83	\$84	\$85	\$86	\$87	\$88	\$89	\$8A	\$8B	\$8C	\$8D	\$8E	\$8F
Row 2	\$C0	\$C1	\$C2	\$C3	\$C4	\$C5	\$C6	\$C7	\$C8	\$C9	\$CA	\$CB	\$CC	\$CD	\$CE	\$CF

As an example, if a hex \$82 is received from the G4 this would indicate the cursor location is on ROW 1, COLUMN 3.

This ‘ON’/‘OFF’ control corresponds to the view ability and style of the cursor. An ‘ON’ setting makes the cursor viewable, an ‘OFF’ setting makes the cursor invisible. The table below shows the various cursor control codes.

CURSOR TYPE	CONTROL	HEX CODE
Show Cursor	ON	Hex \$0E
Hide Cursor	OFF	Hex \$0C
Cursor Flash	ON	Hex \$0D

Cursor Control Codes

Referring to Figure 6A there is shown a card reader and user interface system 600. The card reader and user interface system 600 can be manufactured into a card reader processor interface board 312 and as shown in Figure 3B fastened to the card reader assembly. In an exemplary embodiment system 600 is a computing platform that interconnects with system 500's interactive interface 532. In this regard the credit card and user interface 600 provide a user with user interface and display means for transacting a cashless transaction.

Interconnected with microcontroller 602 can be an input and output (I/O) interface 604. I/O interface 604 can be a plurality of data communication lines and or a plurality of communication ports such as RS232, RS485, or other similar I/O interfacing configurations. In an exemplary embodiment I/O interface 604 can be used to implement electrical interface connections to other peripheral devices. Microcontroller 602 can be any suitable microcontroller, or microprocessor. In an exemplary embodiment a microcontroller 602 can be a MICROCHIP PIC16F876-20/SP, PIC16C76-20/SP, ZILOG, MOTOROLA, UBICOM, INTEL or other similar microcontroller or microprocessor.

Interconnected with microcontroller 602 can be a display 606. Display 606 can provide message prompts and other visual information to a user. Display 606 can be any suitable display, LCD display, or flat panel display. In an exemplary embodiment a display 606 can be an OPTREX DMC-16202-NY-LY or a 16x2 line LCD character display.

A printer interface 608 can be interconnected with microcontroller 602. A printer interface 608 can be a serial communication style or Centronic style interface. In an

exemplary embodiment printer interface 608 can be utilized to print receipts, coupons, and other print data.

Interconnected with microcontroller 602 can be a card reader interface 610. Card reader interface 610 can support a variety of card reader interfaces and protocols including for example and not limitation bit strobe type of card readers. Bit strobe type of card readers read predefined tracks of data from a magnetic card. To read track data the card reader can incorporate a plurality of DATA lines and DATA CLOCK lines to transfer magnetic card data. Card reader interface 610 can also support serial communications style card readers. Serial communication style card reader can incorporate TRANSMIT, RECEIVE, CLEAR TO SEND, REQUEST TO SEND control lines to transfer card data to system 500 via data communication between the interactive interfaces 532 and 614. Such magnetic card readers can include those manufactured for or by XICO, MAGTEK, NEURON, or other similar or suitable card reader.

Interconnected with microcontroller 602 can be a plurality of keypad and button inputs 612. Push button switch 308 can be electrically interconnected with button inputs 612.

An interactive interface 614 can be interconnected to microcontroller 602. The interactive interface 614 operates in similar form and function to interactive interface 532.

Referring to Figure 6B there is shown a card reader and user interface system 600 data communication routing switch. In an exemplary embodiment system 600 is manufactured onto the card reader and user interface board 312. Furthermore, system 500 is manufactured into VIU 100. The card reader assembly and optional printer assembly are then installed into vending equipment in such a way as to allow user access to the

front faceplate 302 of the card reader assembly. Since in many cases there is little room in the vending equipment door area it is more convenient to mount the VIU 100 assembly in a different location within the vending equipment. In order to facilitate correct operation of the card reader assembly it must be electrically connected to the VIU 100.

- 5 To minimize the number of electrical connection to a single cable connected between the systems 500 and 600 a cable connection between interactive interfaces 532 and 614 can be implemented.

10 To utilize a single data communication line (transmit line and receive line) a plurality of different types of data need to be combined into a single data stream. To effectuate the combination of data into a single data stream the interactive interface communication protocol shown in the table above can be employed. To decode the data stream and route the data to its correct destination device the data communication routing switch in Figure 6B can be implemented.

15 Referring to Figure 6B there is shown an interactive interface 614 interconnected with microcontroller 602. Microcontroller 602 receives the data communication stream from the system 500's interactive interface 532 and by way of the interactive interface protocol shown in the table above decodes and routes the data to the appropriate
20 peripheral devices. Peripheral devices shown include I/O interface 604, display 606, printer interface 608, card reader interface 610, and keypad and button inputs 612.

25 For example and not limitation print data can be packaged with the format and control codes outline in the interactive interface protocol and specification shown in the table above. Upon the data arriving at microcontroller 602, microcontroller 602 can decode that the data is print data, remove any protocol formatting characters to obtain pure print data, and then pass or forward the data to the printer interface 608. Similar processes can occur for the other peripheral devices including I/O interface 604, display

606, and card reader interface 610, and keypad and button inputs 612. Data can also be obtained from each of the peripheral devices and combined into a single data string. The data string can be sent to the system 500 where processing can occur based in part of the data string received.

5

Referring to Figure 7 there is shown a transceiver and modem base unit system 700 and a plurality of remote locations 804, 806, 808, 810 including a plurality of global network based data processing resources. Remote locations 804, 806, 808, and 810 can be Internet based, accessible by the Internet, or be a global network based data processing resource. In general Internet based and Internet accessible resources can be referred to as global network based data processing resources. For purposes of disclosure remote location can be referred to as remote location 804, 806, 808, and 810 and can also be referred to as global network based data processing resources.

10

15

One aspect of equipping vending equipment with a VIU 100 and or a card reader assembly and optional printer assembly is that the VIU 100 device requires a data communication connection with a plurality of remote locations. In many vending equipment locations it can be difficult to connect the VIU 100 to a physical communication line. When connecting the VIU 100 to a physical communication is difficult or undesirable the use of the transceiver and modem base unit 700 (also referred to as base unit 700) can be a more preferred data communication option. A transceiver and modem base unit 700 can be referred to as a transceiver unit 700. Transceiver unit 700 is incorporated into transceiver and modem base unit 200.

20

25

In an exemplary embodiment the transceiver unit 700 forms a wireless data link with a VIU 100 have a system 500 incorporated within. In this regard the requirement of physically connecting the VIU 100 to a communication line can be eliminated. To create a wireless data line the VIU 100 equipped with an audit-credit-interactive system 500

utilizes transceiver 524 to data communicate with transceiver unit 700's transceiver 708. Transceiver 708 is interconnected with microcontroller 702. An antenna 716 is interconnected with transceiver 708. Antenna 716 can be of similar form and function to antenna 538. Transceiver 708 can be similar in form and function to transceiver 524.

5

Microcontroller 702 receives and decodes data packet information. Data packets can include command data for configuring the transceiver unit 700 and or data intended to be passed or forwarded to a plurality of remote locations by way of modem 704. Microcontroller 702 can be interconnected with modem 704. Modem 704 can be similar in form and function to modem 522.

10

Also interconnected with microcontroller 702 can be at least one of the following: a wireless interface 720, a network connection 722, an interactive interface 718, or a serial interface 724. Wireless interface 720, network connection 722, and interactive interface 718 can be referred to as a communication interface or base unit 700 communication interface. Wireless interface 720 can be similar in form and function to external modem interface 528 and or data modem 514. Network connection 722 can be similar in form and function to network interface 542. Interactive interface 718 can be similar in form and function to interactive interface 532. Serial interface 724 can be similar in form and function to interactive interface 532.

15

20

A plurality of remote locations can include credit bureaus such as processing bureau 804, host network centers such a host network center 808, other remote location such as remote location 806, and global network based data processing resource 810. Processing bureau 804, host network center 808, and remote location 806 can be referred to as a plurality of remote locations or remote locations. Processing bureau 804 can be a credit card processing bureau. Remote location 810 can be an Internet based data

25

processing device or resource, or a device or resource accessible by way of the Internet – thus referred to as a global network based data processing resource.

Microcontroller 702 can be any suitable microcontroller, or microprocessor. In an exemplary embodiment a microcontroller 702 can be a MICROCHIP PIC16F876-20/SP, PIC16C76-20/SP, ZILOG, MOTOROLA, INTEL, UBICOM, or AMD.

Referring to Figure 8 there is shown an audit-credit-interactive system 500 interfaced to a computing platform. Figure 8 illustrates how a audit-credit-interactive system 500 can be data communication connected to a computing platform 802 by way of system 500's interactive interface 532 and computing platform 802 interactive interface. In similar form and function as the interactive interface solution between system 500 and system 600 described above, system 500 and computing platform 802 can interconnect and data communicate as described with the communication specification and protocol shown in the table above.

There can be at least two method of interconnecting a system 500's interactive interface 532 to a computing platform 802. In the first method the system 500 and the computing platform 802 can be mutually exclusive devices that share a data cable connection between the interactive interfaces. In this regard the system 500 could be manufactured separate from the computing platform 802 and later during installation interconnected together with a data cable connection between the interactive interface ports.

This method allows maximum flexibility in the selection of the computing platform 802's form and functional features as well as allowing maximum flexibility in the selection of the system 500's form and functional features.

A second method of interconnecting a system 500's interactive interface 532 to a computing platform 802's interactive interface can be to integrate the system 500 and computing platform 802 into a single circuit design, preferably manufactured into a single circuit board device, semiconductor chip, or module. In this regard the VIU 100 could comprise an integrated system 500 and computing platform 802 combined. This method of interconnectivity can be desirable, for example and not limitation, when mass-produced VIU 100's with a computing platform option is required, and where cost, unit size, and or ease of installation and service are considerations.

Referring to Figure 9A there is shown a vending machine MULTI-DROP-BUS interface with a plurality of peripheral devices interconnected thereto. In typical vending equipment that operates with a VMC having a vending machine MDB interface 902 that supports the NAMA MDB specification, peripheral device can be interconnected to the vending equipment's common MDB bus. Once the peripherals are connected to the MDB bus the VMC is designated to operate as the master device and each of the peripheral devices are designated as slave peripheral devices. Such slave peripheral devices can include bill acceptor 904, coin mechanism 906, card reader 908, and online module 910.

Bill acceptor 904 and coin mechanism 906 can be of a type for example and not limitation manufactured for or by MARS, COINCO, CONLUX, or other similar bill acceptor and coin mechanism type or manufacturer. Card reader 908 can be of a type for example and not limitation manufactured by or for USA TECHNOLOGIES, MARS, MARCONI, DEBITEK, SCHLUMBERGH, ACT, COINCO, EVEND, WIRCA, US WIRELESS or other similar card reader type. Online module can be of a type for example and not limitation manufacture for or by USA TECHNOLOGIES, MARCONI, MARS, COINCO, WIRCA, US WIRELESS, EVEND or other similar online module type.

A limitation on peripheral devices can be that they must support a compatible version of the MDB protocol specification to operate correctly. This requirement of having to support the version of MDB protocol the VMC supports can limit the selection of compatible peripheral devices as well as limit the range of functionality of the peripheral devices.

For example and not limitation if the VMC MDB protocol version does not support obtaining audit information from a peripheral device the audit information contained within the peripheral device will go unutilized. If in another example the bill acceptor is able to report it's functional operation information and the VMC does not support a MDB protocol version to obtain this information the data in the bill acceptor will not be retrieved and the benefits of having such informational data will not be realized.

Figure 9B illustrates how an audit-credit-interactive system 500 can be configured in series with the vending machine MDB interface 902. In this regard, the peripheral devices can be supported by the system 500's mimic MDB interface 516. The advantage off this network configuration is that the system 500 can support multiple versions and derivative versions of the NAMA MDB protocol specification. Furthermore, the system 500 can provide peripheral message emulation and message passing to effectuate the VMC's ability to data communicate to each peripheral by way of the system 500's MDB interface 518 and mimic MDB interface 516.

In an exemplary embodiment the VMC can data communicate with each peripheral device at the MDB version level of the VMC. In addition, system 500 can data communicate with the VMC and each peripheral device at the VMC version level and each peripheral MDB version or derivative version level. In this regard features supported by a peripheral device's MDB version or derivative MDB version can be

utilized. In addition, data communication between the system 500 and each peripheral device effectuates the ability to remotely monitor and manage each peripheral. In this type of peripheral support system 500 servers as a data communication gateway for each peripheral device. System 500 ability to data communicate with a plurality of remote
5 location and with each peripheral device effectuates the ability of each peripheral device to data communicate with a plurality of remote locations.

Referring to Figure 9B there is shown a system 500's MDB interface 518
interconnected with the VMC vending machine interface 902. In this relationship the
10 system 500 can support the version of MDB protocol that the VMC firmware supports. Each of the peripheral devices including bill acceptor 904, coin mechanism 906, card reader 908, and online module 910 can then be interconnected with the system 500's mimic MDB interface 516. In this regard the system 500 can support any number of NAMA MDB protocol versions and or derivative versions of the NAMA MDB protocol.
15

For example and not limitation if the VMC supports NAMA MDB version 1.0 and an online module 910 supports a derivative version of the NAMA MDB protocol called advanced version 3.0 both the VMC and the online module 910 can be
interconnect to a system 500 and operate correctly. In this relationship system 500 by
20 way of MDB interface 518 and mimic MDB interface 516 data communicates with both the VMC and online module 910. The system 500 interrupts and emulates the correct device protocols as to allow the VMC to data communicate with the online module 910.

In addition, the system 500 can data communicate with the online module for the
25 purpose of effectuating MDB command messages not supported by the VMC's MDB version. The system 500 can then selectively data communicate, to a plurality of remote locations, data related to the peripheral devices including the online module 910.

Furthermore, by way of system 500 the peripheral devices interconnected with the system 500's mimic MDB bus 516 can data communicate with a plurality of remote locations.

Referring to Figure 9C there is shown a audit-credit-interactive system 500 with
5 card reader and audit functionality embodiment interfacing to a vending machine MDB
bus and interfacing to a plurality of peripheral device by way of a audit-credit-interactive
system 500 mimic MDB bus. In an exemplary embodiment system 500 combines the
functionality of the card reader peripheral and audit or as it is commonly referred to as
10 the online module or telemetry function thus eliminating the need for additional
peripheral devices to provide these functions. In addition, the mimic MDB interface 516
can optional support peripheral devices that are not compatible with the vending
equipment's VMC.

Figure 9C illustrates that with a system 500 interconnected with the vending
15 equipment's MDB interface 902 there is created two alternative bus configurations for
the peripheral devices. For example and not limitation the bill acceptor 904, coin
mechanism 906, as well as other types of peripheral devices can, based in part on MDB
version compatibility, reside on either the vending equipment's MDB interface 902, or
the system 500's mimic MDB interface 516.

Referring to Figure 10A there is shown an audit-credit-interactive system 500
embodied in a semiconductor package 1002. In an exemplary embodiment a complete
system 500 can be manufactured into a semiconductor or into a module to support
additional components and or connectivity options. This type of manufacture can have
25 the advantage of small size and low cost. In addition, such a semiconductor version of an
audit-credit-interactive system 500 can be advantageous when integration of system
500's functionality into other electronic device is desirable.

For example and not limitation a bill acceptor, a coin mechanism, or other type of electronic device can have a system 500 embedded into semiconductor 1002 designed into the peripheral device circuitry. In addition to providing system 500 functionality semiconductor 1002 can be soldered or mounted into the peripheral circuit board
5 eliminating the need for additional manufacture and packaging of a system 500.

Figures 10A-10B show a system 500 integrated into semiconductor packaging 1002. Semiconductor package 1002 can also be a module comprising a plurality of electrical components to implement a system 500. Semiconductor package 1002 can be
10 referred to as module 1002. Referring to Figure 10A the system 500 shown includes microcontroller 502 interconnected with card reader interface 526, display interface 508, external peripheral interface 536, interactive interface 532, NOVRAM memory 512, timekeeper 540, flash memory 512, flash memory interface 544, NOVRAM interface
15 546, communication interface 548, and vending equipment interfaces 506, 516, 518, and 520. Other system 500 features can be included as may be required by the application. In addition, system 500 features shown within semiconductor package 1002 can be eliminated as may be required or desirable based on the application.

Timekeeper 540 can be a real time clock (RTC) for keeping track of date and time
20 functions. Flash interface 544 can be an interface to serial and or I²C electrical erasable read only memory (EEROM) or other flash memory types of devices. NOVRAM interface 546 can be a data connection to an external non-volatile read only memory device such as NOVRAM 1004. NOVRAM 1004 can be of similar form and function as NOVRAM 512.

25 External interconnections to semiconductor 1002 can include card reader 1012, display 606, external peripheral 1016, computing platform 802, external flash 1006, communication device 1008, interface to vending equipment 1010, and NOVRAM 1004.

Card reader 1012 can be an industry standard bit strobe, and serial style track 1, 2, and 3 card readers. Such card readers include for example and not limitation those manufactured for or by XICO, NEURON, and MAGTEK.

5

External peripheral 1016 can include RFID readers and writers, biometric devices, common communication ports such as RS232 and RS485, general purpose I/O, keypad, and or other types of peripheral device. External memory 1006 and external memory 1004 can be similar in form and function as memory 512. External communication device 1008 can include a modem, transceiver, network interface, or other type of communication device. Communication device 1008 and communication interface 548 can be similar in form and function to modem 522, transceiver 524, data modem 514, and or network interface 542.

10

15

In an exemplary embodiment where possible software executing within semiconductor 1002 can emulate certain system 500 functionality to further reduce the dependence of physical hardware. For example and not limitation the card reader interface may be implemented in software where general purpose I/O lines could be configured to capture card data received from a card reader such as card reader 1012.

20

Referring to Figure 10B the system 500 is embedded within semiconductor package 1002. In this embodiment the system 500 relies on software executing in microcontroller 502 to implement and emulate the system 500's functionality. In this embodiment software configures general purpose I/O lines to implement card reader interface 526, display interface 508, external peripheral interface 536, interactive interface 532, NOVRAM interface 546, vending equipment I/O 506, 516, 518, and or 520, and communication interface 548.

25

One advantage of implementing system 500 in software can be that the system 500 software solution can be implemented is mass producible generally available microcontroller devices. Such microcontroller devices can include for example and not limitation UBICOM's line of microcontrollers, MOTOROLA, INTEL, MICROCHIP, ZILOG, and other similar or suitable microcontroller or microprocessor devices.

A second advantage of implementing system 500 in software can be that the proprietary nature of the software and its functional capabilities can more easily be concealed and protected when resident and secured within a microcontroller. In addition to the secure ability of the system 500 solutions, implementing a system 500 in a microcontroller brand or series that other design engineers are familiar with can be advantageous in easing the integration of the system 500 semiconductor package 1002 into electrical designs.

Further ease of integration can be achieved by implementing power converter 1020. Power converter 1020 converts input voltage obtained from the vending equipment's MDB bus via the vending machine's MDB interface 902. The output voltage from power converter can be referred to a +VCC and can power the system 500 semiconductor 1002.

One advantage of allowing power convert 1020 to supply power to semiconductor 1002 can be that the semiconductor can be resident on an adapter card and retrofit to existing VMC's by connection to the VMC's MDB interface 902. Through this single connection point the adapter card comprising the semiconductor 1002 can power itself and data communicate with the VMC by way of the VMC MDB interface 902.

Furthermore, the semiconductor 1002 can be integrated into the VMC controller electronics and electrically connected on the circuit board to the VMC MDB interface

902. Simplifying the data and power connections between semiconductor 1002 and the VMC can save time and effort in the integration of the combined VMC/system 500 solution. In addition, the fact that the system 500 can operate mutually exclusive from the VMC can be advantageous in the design of the overall combined VMC/system 500 solution.

Besides combining the system 500 on a chip with a VMC control system the system 500 packaged in semiconductor 1002 can be integrated into a computing platform 802. In this regard the semiconductor 1002 can be integrated into the computing platform 802 electronics and electrically connected by way external peripheral interface 536. In addition, the fact that system 500 can operate mutually exclusive from the computing platform 802 can be advantageous in the design of the overall combined computing platform 802/system 500 solution.

Referring to Figure 11 there is shown an MDB initialization tuning routine 1100. With the proliferation of different kinds and styles for vending equipment VMC controllers the NAMA MDB and NAMA derivative MDB protocol implementation can vary from VMC to VMC. In addition the processing capabilities, UART implementations and lack of UART implementations can cause a variation in VMC microcontroller performances. These performance variations in VMC microcontrollers can cause the serial communications between VMC to vary in the devices ability and speed by which data bytes can be consecutively data communicated to the VMC controller. In addition to data communication speed and response timing another variation between VMC's can be interpretation of protocol command functionality, usage, and messaging formatting.

Another source of VMC MDB protocol implementation variations can occur as a result of the VMC computing power and or microprocessor speed or (millions of instructions per second) MIPS capability. Microprocessor speed can influence MDB

protocol implementation and message transaction speed in several ways. One such way can be in the MDB interface to the microprocessor.

MDB message transactions are a string of serial bytes. As such bytes must arrive
5 one at a time to the VMC microprocessor. Once a byte arrives it must be fetched from the VMC microprocessor receive buffer and processed. The time required to fetch a byte can vary from VMC to VMC. As such the inter-byte time spacing, which is the amount of time delay inserted between sent bytes could be a critical variable. If for example and not
10 limitation a string of bytes arrive to close together, or in other words the inter-byte time spacing is too short the VMC may not be able to process the bytes and as a result the system 500 could fail to initialize and operate correctly. If for example and not limitation a string of bytes arrive to far apart, or in other words the inter-byte time spacing is too long the VMC may time-out and fail to process the MDB message. As a result the system 500 could fail to initialize and operate correctly.

The MDB protocol involves a master-slave relationship between the master
15 vending equipment's VMC and the slave peripheral devices. In implementing the MDB protocol the master VMC initiates an MDB message command to a slave peripheral device. The slave peripheral device then has a finite amount of time to respond the VMC
20 command message with a message response. As such the amount of time allotted for the peripheral device to respond with a MDB message response can vary from VMC to VMC. If for example and not limitation the peripheral device responds too quickly with a message response the VMC's microprocessor may not be ready and miss the return message. As a result the system 500 could fail to initialize and operate correctly. If for
25 example and not limitation the peripheral device takes too much time to respond to the message the VMC may time-out waiting for the peripherals response message. As a result the system 500 could fail to initialize and operate correctly.

The MDB initialization tuning routine 1100 determines through successive iterations of the MDB initialization sequence the optimum inter-byte spacing and message response timing. Processing begins in block 1102.

- 5 In block 1102 the MDB inter-byte time spacing and the MDB response time are set to a minimum range setting. Processing then moves to block 1104. Appropriate inter-byte time spacing can range from a minimum range of a few microseconds to a maximum range of a several milliseconds. Appropriate message response time also referred to as the response time can range from a minimum range of less than one millisecond to a
- 10 maximum range of five to ten milliseconds.

In block 1104 the system 500 waits for the VMC to initiate the POLL command. In response to the POLL command the system 500 sends the JUST RESET command. Processing then moves to block 1106.

- 15 In block 1106 the system 500 responds to VMC MDB transaction messages with message responses in an attempt to initialize the system 500. Processing then moves to decision block 1108. Initialization of the system 500 occurs by a series of successful VMC and system 500 MDB transaction message exchanges. The system 500 can be
- 20 considered successfully initialized when the VMC and the system 500 have exchanged configuration messages and the VMC has issued to the system 500 the MDB ENABLE message.

- In decision block 1108 a determination is made as to whether the system 500
- 25 received the MDB ENABLE command from the VMC and if the system 500's operation state is now enabled. If the resultant is in the affirmative that is the system 500's operation is now ENABLED then the routine is exited. If the resultant is in the negative

that is the system 500's operational state is not ENABLED then processing moves to block 1110.

In block 1110 the inter-byte time spacing is incrementally increased and
5 processing moves to decision block 1112. The incrementing of the inter-byte time spacing can be either automatic in system 500 software or manually changed by service personnel.

In decision block 1112 a determination is made as to whether the inter-byte time
10 spacing maximum range has been reached. If the resultant is in the affirmative that is the inter-byte time spacing maximum range has been reached then processing moves to block 1114. If the resultant is in the negative that is the inter-byte time spacing maximum range has not been reached then processing returns to block 1104.

In block 1114 the inter-byte time spacing is set to the initial minimum range
15 setting. In addition, the message response time is incremented. The incrementing of the message response time can be either automatic in system 500 software or manually changed by service personnel. Processing then moves to decision block 1118.

In decision block 1118 a determination is made as to whether the message
20 response time maximum range has been reached. If the resultant is in the affirmative that is the maximum message response time range has been reached then processing moves to block 1116. If the resultant is in the negative that is the maximum message response range has not been reached then processing moves back to block 1104.

25 In block 1116 a prompt is provided that the MDB communications between the system 500 and the VMC could not be established. The routine is then exited.

Referring to Figures 12A-12B there is shown a VIU 100 with system 500 and transceiver and modem base unit system 700 wireless protocol data communication routine 1200. In a typical application involving a VIU 100 comprising audit-credit-interactive system 500 the VIU 100 will be installed in vending equipment. In certain of those installations it may desirable to data communicate wirelessly to a transceiver system 700 instead of trying to hardwire the system 500 to a communication line. A transceiver system 700 can be referred to as a base unit or base unit 700.

In installations where system 500 data communicates to a plurality of remote locations by way of a wireless data connection to transceiver system 700 a protocol can be implemented to insure data integrity, security, and transceiver system 700 correct configurations. Routine 1200 can implement such a protocol between system 500 and transceiver system 700. Processing begins in block 1202.

In block 1202 the transceiver system 700 data communicates wirelessly an ENQ packet. The 'ENQ' packet comprises control codes that indicate the state and or current condition of the base unit 700. Base unit 700 state or condition codes include an AVAILABLE condition, BUSY condition, and a POLLING condition.

The AVAILABLE state indicates to any VIU 100 system 500 listening in wireless proximity to the base unit 700 that the base unit and communication interface is AVAILABLE and ready for use by any VIU 100. The communication interface includes modem 704, wireless interface 720, interactive interface 718, serial communication interface 724, and network connection 722. In an exemplary embodiment base unit 700 is configured to use one of the communication interface options (704, 718, 720, 722, or 724). The BUSY state indicates to any VIU 100/system 500 listening in wireless proximity to the base unit 700 that the base unit and communication interface is BUSY servicing a different VIU 100 and is unavailable for use. The POLLING state indicates to

any VIU 100/system 500 listening in wireless proximity to the base unit 700 that a remote location has requested that the VIU 100 initiate a call host sequence. This in effect triggers each VIU based on individual VIU 100 programming to initiate a call to the requesting remote location. Processing then moves to decision block 1204.

5

In decision block 1204 a determination is made as to whether the system 500, referred to as the terminal, wirelessly receives the ENQ message sent by the transceiver system 700. If the result is in the affirmative that is the terminal receives the ENQ message then processing moves to block 1206. If the resultant is in the negative that is the terminal did not receive the ENQ message then processing moves back to block 1202.

10

In reply to block 1206 the terminal is enabled for transaction processing. Processing then moves to block 1208.

15

In block 1208 the transceiver system 700 referred to as the base unit transmits an ENQ packet with a packet ID attached. Processing then moves to block 1210.

20

In block 1210 the terminal receives the ENQ and packet ID from the transceiver system 700. In accordance with system 500 data requirements the system 500 then responds as necessary with a data packet. Processing then moves to block 1212.

In block 1212 the transceiver system 700 upon receiving the data packet from the system 500 decodes the data packet. Processing then moves to decision block 1214.

25

In decision block 1214 the transceiver system 700 makes a determination as to whether the data received from the system 500 is data intended for system 700 configurations. System 700 can be referred to as the base unit or base. If the resultant is in the affirmative that is the data is configuration data for the base unit processing moves

to block 1218. If the resultant is in the negative that is the data is not configuration data for the base unit then processing moves to block 1216.

5 In block 1216 the data received from the system 500 is data communicated or passed to the system 700's modem 704. Processing then moves back to block 1208.

10 In decision block 1218 a determination is made as to whether the data command received from the system 500 is a baud rate configuration command intended for modem 704 or a baud rate configuration command intended for transceiver 708.

15 In an exemplary embodiment modem 704 data communicates with microcontroller 702 at a first baud rate to effectuate data communication with a plurality of remote locations. Transceiver 708 data communicates with microcontroller 502 by way of transceiver 524 at a second baud rate to effectuate data communications between system 500 and a plurality of remote locations by way of system 700. The first baud rate and the second baud rate can be the same or different baud rated.

20 If the resultant in decision block 1218 is in the affirmative that is the data command is a baud rate configuration command then processing moves to decision block 1220. If the resultant is in the negative that is the data command received is not a baud rate configuration command then processing moves to decision block 1228.

25 In decision block 1220 a determination is made as to whether the command is intended for modem 704. If the resultant is in the affirmative that is the command is intended for modem 704 then processing moves to block 1224. If the resultant is in the negative that is the command is not intended for modem 704 then processing moves to block 1222.

In block 1220 the transceiver 708 baud rate is configured. Processing moves to block 1226.

5 In block 1224 the baud rate of modem 704 is configured. Processing moves to block 1226.

In block 1226 the transceiver system 700 sends the acknowledge (ACK) message to the system 500 originating the data command. Processing then move backs to block 1208.

10

In decision block 1228 a determination is made as to whether the received data command is a hardware-reset command. If the resultant is in the affirmative that is the received data command is a hardware-reset command then processing moves to decision block 1230. If the resultant is in the negative that is the received data command is not a hardware-reset command then processing moves to block 1234.

15

In decision block 1230 a determination is made as to whether the received command is a modem hardware-reset command. If the resultant is in the affirmative that is the received data command is a modem hardware-reset command then processing moves to block 1232. If the resultant is in the negative that is the data command received is not a hardware-reset command then processing moves to block 1236.

20

In block 1232 the transceiver system 700 sends the ACK message to the system 500 originating the data command. Processing then move to block 1238.

25

In block 1238 the microcontroller 702 is reset. The routine is then exited.

In block 1236 the modem 704 is reset. Processing moves to block 1240.

In block 1240 the transceiver system 700 sends the ACK message to the system 500 originating the data command. Processing then move backs to block 1208.

5 In block 1234 the transceiver system 700 sends the COMMAND NOT RECOGNIZED message to the system 500 originating the data command. Processing then move backs to block 1208.

10 Referring to Figure 20 there is shown a transceiver and modem base unit system 700 wireless protocol data communication routine 2000. In an exemplary embodiment the base unit 700 serves as a data gateway between the system 500 and a remote location. In operation the system 500 1) initially requests data access to the base unit 700, and if data access is granted by the base unit 700 then 2) begins utilizing the base unit 700 internal modem by transmitting and receiving data packets to and from the base unit 700. 15 The base unit 700 manages 1) granting or denying data communication access between the system 500 terminal and the base unit 700, 2) the receiving of packetized wireless data from the system 500 for processing and data communication to the internal base unit 700 modem 704, and 3) the receiving of data from the internal base unit 700 modem, processing, packetizing, and wireless data communication via transceiver 708 to the 20 system 500 terminal.

The data packets and wireless communication protocol can be encrypted, and error checked for data integrity. In addition, the remote hosts both credit bureau and the USALIVE network can perform their own data integrity checking. In essence the data 25 packets can be error checked and the data received at the hosts can be error checked.

In an exemplary embodiment the packet by packet error checking can be turned off at the base unit 700 and system 500 and the data packets can be automatically sent

multiple time. In this regard, error checking of each packet still occurs and only correct error free packets are passed to the remote location. Packets with errors are just discarded. If an error in a packet is detected it is the successive sending of the same packet that is relied upon to overcome the error. With no ACKing or NAKing on a packet by packet basis a half duplex transceiver system can send more data faster by not having to switch between send and receive modes. Since the remote location has calculated its own checksums and appended it to the data the remote location can determine if all data was received and received correctly. If the determination is made at the remote location that the data was not received correctly then the remote location can data communicate a NAK and the system will retransmit the data.

The wireless communication protocol comprises a successive try-retry algorithm to insure the wireless data transmission is received complete and error free. In the event wireless data can't be transmitted error free or packets are missing the system 500 has embedded programmable functionality to compensate for the dropped transmission.

In an exemplary embodiment, in the event the system 500 is trying to real time authorize a credit card with a remote credit bureau and the system is unable to wirelessly complete the task; instead of failing the process entirely the system 500 can terminate the wireless transmission and rely on its own internal local authorization routines 1300 or 1900 to validate the user's credit card.

In a second exemplary embodiment, if the system 500 is trying to data communicate wirelessly with a remote host location such as USALIVE and the wireless communication fails the communication can be automatically rescheduled by the system 500 terminal.

Routine 2000 details the process of wireless data communication between the system 500 terminal and a remote location and or a global network based data processing resource such as global network based data processing resources 810 by way of the base unit 700.

5

Processing begins block 2002 where the VIU 100 listens for the 'ENQ' status packet communicated from the base unit 700. The 'ENQ' packet comprises control codes that indicate the state and or current condition of the base unit 700. Base unit 700 state or condition codes include an AVAILABLE condition, BUSY condition, and a POLLING condition.

10

The AVAILABLE state indicates to any VIU 100 system 500 listening in wireless proximity to the base unit 700 that the base unit and communication interface is AVAILABLE and ready for use by any VIU 100. The communication interface includes modem 704, wireless interface 720, interactive interface 718, and network connection 722. In an exemplary embodiment base unit 700 is configured to use one of the communication interface options (704, 718, 720, or 722).

15

The BUSY state indicates to any VIU 100 system 500 listening in wireless proximity to the base unit 700 that the base unit and communication interface is BUSY servicing a different VIU 100 and is unavailable for use.

20

The POLLING state indicates to any VIU 100 system 500 listening in wireless proximity to the base unit 700 that a remote location has requested that the VIU 100 initiate a call host sequence. This in effect triggers each VIU based on individual VIU 100 programming to initiate a call to the requesting remote location. If the current state or condition of the base unit 700 is BUSY or POLLING then the routine is exited, else processing moves to decision block 2022.

25

In decision block 2022 where a determination is made as to whether a system 500 terminal is requesting wireless data communication access to the base unit 700. If the resultant is in the affirmative that is there is a system 500 requesting wireless data
5 communication access to the base unit 700 then processing moves to decision block 2004. If the resultant is in the negative that is there is no system 500 requesting data communication access to the base unit 700 then the routine is exited.

In decision block 2004 a determination is made as to whether the base unit 700 is
10 sharing a telephone line with additional equipment, such as a fax machine. If the resultant is in the affirmative that is the base unit 700 is sharing a telephone line then processing moves to decision block 2006. If the resultant is in the negative that is the base unit 700 is not sharing a telephone line with additional equipment then processing moves to block 2008.

In decision block 2006 a determination is made as to whether the shared
15 telephone line is currently in use by the additional or shared equipment. If the resultant is in the affirmative that is the telephone line is in use then processing moves to block 2010. If the resultant is in the negative that is the telephone line is available and not in use then
20 processing moves to block 2008.

In block 2010 upon the determination that the telephone line is not available the
base unit 700 wirelessly notifies the requesting system 500 that the telephone line is in
use. The system 500 depending on feature programming then makes a determination as to
25 whether to invoke the local authorization routines 1300 or 1900 or reschedule the data communication attempt to the remote host network. The routine is then exited.

In block 2008 the base unit 700 wirelessly notifies the requesting system 500 that the telephone line is available and data communication between the requesting system 500 and the base unit 700 can begin. In addition, the base unit 700 notifies any other system 500 in wireless proximity to the base unit that the base unit 700 is currently
5 unavailable. Processing then moves to block 2012.

In block 2012 the system 500 begins packetizing the desired data and wirelessly data communicating with the base unit 700. Less the packetizing data and processing, the system 500 in large part data communicates the same data that would be required to
10 initialize a modem and effectuate modem dialing if the modem were physically present on the system 500 circuit card. Processing moves to block 2014.

In block 2014 wireless data packets received at the base unit 700 from the system 500 are validated and acknowledged. The packet is then parsed and the desired data is
15 passed to the base unit's internal modem 704. A system 500 time-out detection and or base unit 700 non-acknowledge facilitates a retransmission of the data from the system 500. Processing moves to block 2018.

In block 2018 data received at the base unit's microcontroller 702 from the base
20 unit's internal modem 704 is packetized and wirelessly data communicated via transceiver 708 to the appropriate system 500. The data received at the system 500 is validated and optionally acknowledged. A base unit 700 time-out detection and or system 500 non-acknowledge facilitates a retransmission of the data from the base unit 700. Processing then moves to decision block 2016.

25 In an exemplary embodiment data is successively and continuously handled in block 2014 and 2016 as long as data communication between the system 500 and the base unit 700 is required. The base unit 700, system 500, or the remote host can terminate

data communication. Where the remote host is typically the credit card bureau, or USALIVE network.

In decision block 2016 a determination is made as to whether the data communication between the system 500 and the remote host by way of the base unit 700 is complete. If the resultant is in the affirmative that is the data communication is complete then processing moves to block 2020. If the resultant is in the negative that is the data communication is not complete then processing moves back to block 2014.

In block 2016 data communication between the G4 system, the base unit 700, and the remote host is terminated. The base unit 700 notifies all system 500s in wireless proximity to the base unit 700 that the base unit 700 is available. The system 500 concludes data communication and resumes normal terminal functionality. The routine is then exited.

Referring to Figure 13 there is shown a local transaction authorization routine 1300. A conventional card authorization through a remote processing bureau utilizing dial-up landline access to the remote processing bureau can take ten or more seconds to complete. In certain vending venue and or while vending certain type of products a ten or more second delay may be unacceptable. In these instances authorization routine 1300 can be implemented to reduce or eliminate the authorization delay while maintaining a high confidence that the card is valid. A card can be any form of ID including a credit card, magnetic card, wireless phone, a personal digital assistant PDA, private label card, smart card, hotel room card, radio frequency RFID identification, biometric, and or other similar or suitable form of ID. Processing begins in decision block 1302.

In decision block 1302 a determination is made as to whether the LOCAL AUTHORIZATION FLAG is set for this pass. In an exemplary embodiment system 500

can be programmed to locally authorize a card based in part on an iterative process, which allows for the local authorization routine to be invoked, at a minimum, on the first pass and subsequently at any successive pass up to the last pass. The current pass through the routine is referred to as the CURRENT AUTHORIZATION ATTEMPT. The last
5 pass is predetermined and is referred to as the MAXIMUM AUTHORIZATION ATTEMPTS LIMIT. The LOCAL AUTHORIZATION FLAG determines on which iterative pass the local authorization routine will be invoked. The iterative pass in which the LOCAL AUTHORIZATION FLAG will be set and the local authorization routine invoked is referred to as the LOCAL AUTHORIZATION ROUTINE ENTRY
10 COUNTER.

In a first example and not limitation the local authorization can be invoked on the first pass. In this case no remote location will be contacted unless the local authorization results in a declined card response. In a second example the local authorization flag may
15 be set for the second pass. In this case the system 500 will first try to remotely authorize the card. If the remote processing bureau is unavailable or unable to authorize the card then on the second pass the local authorization routine will be invoked.

If the resultant in decision block 1302 is in the affirmative that is the LOCAL
20 AUTHORIZATION flag is set then processing moves to decision block 1304. If the resultant is in the negative that is the LOCAL AUTHORIZATION flag is not set then processing moves to block 1308.

In decision block 1304 a determination is made as to whether the local
25 authorization test was OK. If the resultant is in the affirmative that is the local authorization test was OK then processing moves to decision block 1306. If the resultant is in the negative that is the local authorization test failed then processing moves to block 1308.

In an exemplary embodiment the local authorization test can include a test of the cards expiration date and the cards modulo-10 check digit. The test of the expiration date will determine whether or whether not the card is expired based on the current date. The
5 test for the modulo-10 check digit will determine if the card number sequence is a valid number sequence.

In decision block 1306 a determination is made as to whether the CARD USAGE
10 FREQUENCY LIMIT has been reached. The CARD USAGE FREQUENCY is the total amount of time in a predetermined time period the current card has previously been authorized. In an exemplary embodiment the CARD USAGE FREQUENCY can be used to limit the number of times a card will be locally authorized before the system 500 will attempt to authorize the card by way of a processing bureau 804.

15 If the resultant in decision block 1306 is in the affirmative that is the CARD USAGE FREQUENCY is within the limit then processing moves to decision block 1310. If the resultant is in the negative that is the CARD USAGE FREQUENCY has been reached the limit then processing moves to block 1308.

20 In block 1308 system 500 initiates a data communication for the purpose of authorizing the current card with the processing bureau 804. Processing moves to block 1312.

25 In block 1312 a local database within system 500 can be updated. This local data can include positive cards, which are cards that have previously been successfully approved. In addition, this local database can include negative cards, which are cards that have previously been declined. Processing then moves to decision block 1314.

In decision block 1310 the card is tested for its appearance in the system 500 local databases. If the resultant is in the affirmative that is the card does not appear in a negative database and or the card appears in the positive database then processing moves to block 1312. If the resultant is in the negative that is the card appears in the negative database and or does not appear in the positive database then processing moves to block 1308.

In decision block 1314 a determination is made as to whether the card has been approved. If the resultant is in the affirmative that is the card has been approved then processing moves to block 1316. If the resultant is in the negative that is the card has been declined than processing moves to decision block 1318.

In decision block 1318 a determination is made as to whether the MAXIMUM AUTHORIZATION ATTEMPTS LIMIT has been reached. The MAXIMUM AUTHORIZATION ATTEMPTS LIMIT is the count of the number of iterative authorization passes through routine 1300. If the resultant is in the affirmative that is the MAXIMUM AUTHORIZATION ATTEMPTS LIMIT has not been reached then processing moves back to decision block 1302. If the resultant is in the negative that is the MAXIMUM AUTHORIZATION ATTEMPTS LIMIT has been reached then the routine is exited the card is reported as declined.

In block 1316 the transaction is reported as authorized and the vending equipment is enabled for operation. The routine is then exited.

Referring to Figures 19A-19B there is shown a local authorization routine 1900. Routine 1900 is an exemplary embodiment of a local authorization routine. Routine 1900 utilize locally stored databases to selectively approve and decline a card transaction. Similar to routine 1300, routine 1900 can be implemented to reduce or eliminate the

authorization delay while maintaining a high confidence that the card is valid. A card can be any form of ID including a credit card, magnetic card, wireless phone, a personal digital assistant PDA, private label card, smart card, hotel room card, radio frequency RFID identification, biometric, and or other similar or suitable form of ID. Processing
5 begins in decision block 1902.

In decision block 1902 a test is performed to determine if the card presented is expired. If the resultant is in the affirmative that is the card is expired then processing moves to block 1914. If the resultant is in the negative that is the card is not expired then
10 processing moves to decision block 1904.

In decision block 1904 a test is performed to determine if the modulo-10 of the card presented is correct. If the resultant is in the affirmative that is the modulo-10 check digit match then processing move to decision block 1906. If the result is in the negative
15 that is the modulo-10 check digit does not match then processing moves to block 1914.

In block 1914 the transaction authorization is declined and the routine is exited.

In decision block 1906 a test is made to determine in the MAXIMUM
20 APPROVAL RESET HOUR has been reached. If the resultant is in the affirmative that is the MAXIMUM RESET HOUR has been reached then processing moves to block 1910. If the resultant is in the negative that is the MAXIMUM RESET HOUR has not been reached then processing moves to decision block 1908.

In block 1910 the APPROVAL database is erased and the MAXIMUM RESET
25 HOUR timer is reset. Processing than moves to decision block 1908.

The MAXIMUM RESET HOUR is a remotely programmable preset condition that indicates the time interval in hours between erasing of the APPROVAL DATABASE. In an exemplary embodiment, under normal system 500 terminal use card data can be added to the APPROVAL database each time a valid card is locally authorized. Over time the MAXIMUM OCCURRENCE WARNING LIMIT, and the MAXIMUM OCCURRENCE STOP LIMIT will be reached. Upon exceeding these limits, the system 500 terminal will attempt to authorize the card remotely. If it is the intention to allow a user to locally authorize a card, for example each day, without requiring an occasional remote authorization, but to limit the amount of local authorizations granted in a single day the MAXIMUM RESET HOUR can be set for example and not limitation 24 hours. This will erase the APPROVAL database every 24 hours. As long as the repeat user does not exceed the MAXIMUM OCCURRENCE WARNING or STOP limits in a single 24-hour period no remote authorization will be required. The MAXIMUM RESET HOUR can be set to any amount of time including zero. In the case the MAXIMUM RESET HOUR is set to zero the APPROVAL database will not be cleared automatically base on time.

In decision block 1908 a determination is made as to whether the LOCAL AUTHORIZATION FLAG is set for this pass. In an exemplary embodiment system 500 can be programmed to locally authorize a card based in part on an iterative process, which allows for the local authorization routine to be invoked, at a minimum, on the first pass and subsequently at any successive pass up to the last pass. The current pass through the routine is referred to as the CURRENT AUTHORIZATION ATTEMPT. The last pass is predetermined and is referred to as the MAXIMUM AUTHORIZATION ATTEMPTS LIMIT. The LOCAL AUTHORIZATION FLAG determines on which iterative pass the local authorization routine will be invoked. The iterative pass in which the LOCAL AUTHORIZATION FLAG will be set and the local authorization routine

invoked is referred to as the LOCAL AUTHORIZATION ROUTINE ENTRY COUNTER.

In a first example the local authorization can be invoked on the first pass. In this case no remote location will be contacted unless the local authorization results in a declined card response. In a second example the local authorization flag may be set for the second pass. In this case the system 500 will first try to remotely authorize the card. If the remote processing bureau is unavailable or unable to authorize the card then on the second pass the local authorization routine will be invoked.

If the resultant in decision block 1908 is in the affirmative that is the LOCAL AUTHORIZATION flag is set then processing moves to decision block 1912. If the resultant is in the negative that is the LOCAL AUTHORIZATION flag is not set then processing moves to block 1926.

In decision block 1912 a test is performed to determine is the card presented for authorization is currently in the local DECLINED database. Is the resultant is in the affirmative that is the card is in the DECLINED database then processing moves to block 1926. If the resultant is in the negative that is the card is not in the DECLINED database then processing moves to block 1916.

In block 1916 the APPROVED database is queried to determine how many occurrences of the current card are already in the database (having previously been presented and locally authorized). This is referred to as the NUMBER OF CARD OCCURRENCE IN APPROVED DATABASE. Processing then moves to block 1920.

In block 1920 a comparison of the NUMBER OF CARD OCCURRENCES IN APPROVED DATABASE is made to the MAXIMUM OCCURRENCES WARNING LIMIT. Processing then moves to decision block 1918.

5 The MAXIMUM OCCURRENCES WARNING LIMIT is a remotely programmable preset variable that indicates the number of repeat occurrences the same card number can be presented for local authorization before a remote authorization is forced. In an exemplary embodiment, it may be desirable to accept for local authorization a card no more the 2 time before that card will be authorized at a remote location. The
10 presumption is that only the remote location has access to real time card data validity. In that case a card may be locally authorized that is in fact not a valid active card. To minimize the risk of authorizing a bad card the MAXIMUM OCCURRENCES WARNING LIMIT can be set as desired to limit exposure on a bad card. For example and not limitation the MAXIMUM OCCURRENCE WARNING LIMIT can be set to
15 two. In this case the card will be accepted and locally authorized twice before a remote authorization step is forced.

 In decision block 1918 a test is performed to determine if the NUMBER OF
20 CARD OCCURRENCES IN APPROVED DATABASE exceed the MAXIMUM OCCURRENCE WARNING LIMIT. If the resultant is in the affirmative that is the NUMBER OF CARD OCCURRENCES IN APPROVED DATABASE exceed the MAXIMUM OCCURRENCE WARNING LIMIT then processing moves to block 1926. If the resultant is in the negative that is the NUMBER OF CARD OCCURRENCES IN
25 APPROVED DATABASE does not exceed the MAXIMUM OCCURRENCE WARNING LIMIT then processing moves to block 1922.

 In block 1922 the card data is added to the APPROVED database and the transaction is approved. Processing moves to block 1924.

In block 1924 the transaction is authorized and the user is allowed to utilize the vending equipment. The routine is then exited.

5 In block 1926 system 500 initiates a remote data communication for the purpose of authorizing the current card with the processing bureau 804. Processing moves to decision block 1930.

10 In decision block 1930 a test is performed to determine if during the remote authorization process a communication line failure was detected. Such a failure could include for example and not limitation a phone line being busy or unavailable, or a server being unavailable. If the resultant is in the affirmative that is a communication line failure was detected then processing moves to block 1928. If the resultant is in the negative that is a communication line failure was not detected then processing moves to decision block 15 1934.

In block 1928 the APPROVED database is queried to determine how many occurrences of the current card are already in the database (having previously been presented and locally authorized). This is referred to as the NUMBER OF CARD 20 OCCURRENCE IN APPROVED DATABASE. Processing then moves to block 1932.

In block 1932 a comparison of the NUMBER OF CARD OCCURRENCES IN APPROVED DATABASE is made to the MAXIMUM OCCURRENCES STOP LIMIT. Processing then moves to decision block 1918.

25

The MAXIMUM OCCURRENCES STOP LIMIT is a remotely programmable preset variable that indicates the number of times the same card number can be presented for local authorization before a remote authorization is forced. In an exemplary

embodiment, it may be desirable to accept for local authorization a card no more than three times before that card will be authorized at a remote location.

The difference between the MAXIMUM OCCURRENCE WARNING LIMIT
5 and the MAXIMUM OCCURRENCE STOP LIMIT is that when the WARNING limit is
exceeded a remote authorization will be attempted. If the remote authorization attempt
fails due to communication related issues then the STOP limit will serve as a determinant
in approving or denying the current transaction. If the STOP limit is not exceeded the
local authorization processing will continue. If the STOP limit is exceeded the card will
10 be declined. This feature in affect minimizes the possibility of inadvertently declining a
card based on a communication line failure.

In decision block 1940 a test is performed to determine if the NUMBER OF
CARD OCCURRENCES IN APPROVED DATABASE exceed the MAXIMUM
15 OCCURRENCE STOP LIMIT. If the resultant is in the affirmative that is the NUMBER
OF CARD OCCURRENCES IN APPROVED DATABASE exceed the MAXIMUM
OCCURRENCE STOP LIMIT then processing moves to block 1942. If the resultant is in
the negative that is the NUMBER OF CARD OCCURRENCES IN APPROVED
DATABASE does not exceed the MAXIMUM OCCURRENCE STOP LIMIT then
20 processing moves to block 1944.

In block 1944 the card data is added to the APPROVED database and the
transaction is approved. Processing moves to block 1946.

25 In block 1946 the transaction is authorized and the user is allowed to utilize the
vending equipment. The routine is then exited.

In decision block 1934 a test is made to determine if the card was approved. If the resultant is in the affirmative that is the card was approved then processing moves to block 1938. If the resultant is in the negative that is the card was declined then processing moves to block 1936.

5

In block 1936 the card is entered into the DECLINED database. If multiple occurrences of the card appear in the DECLINED database the duplicate occurrences are removed. Processing then moves to block 1942.

10

In block 1938 all occurrences of the card data are removed from the APPROVED database. The transaction is approved and processing moves to block 1946.

15

Referring to Figure 14 there is shown an international transaction authorization and settlement routine 1400. Standard transaction processing fees for low cost sales can be significant. International card processing can incur even more transaction processing fees in the form of currency conversion fees. Currency conversion fees are fees incurred when currency is converted from one countries currency to another. To minimize the standard transaction processing fees and to minimize and or eliminate the currency conversion fees routine 1400 can be implemented. Processing begins in block 1402.

20

In block 1402 the local authorization routine 1300 is executed. Processing moves to decision block 1404.

25

In decision block 1404 a determination is made as to whether a remote data communication to a processing bureau 804 is required. If the resultant is in the affirmative that is the local authorization is approved and a remote authorization is not required then processing moves to block 1408. If the resultant is in the negative that is the

local authorization was declined or failed and a remote data communication with processing bureau 804 is required then processing moves to block 1406.

5 In block 1406 authorization through a network connection to a remote host network 808 and or processing bureau 804 is executed. Processing then moves to decision block 1418.

10 In decision block 1418 a determination is made as to whether the remote authorization was approved. If the resultant is in the affirmative that is the remote authorization was approved then processing moves to block 1408. If the resultant is in the negative that is the remote authorization failed or was declined then the card is declined and the routine is exited.

15 In block 1408 the vending equipment is enabled and vending can occur. Processing then moves to block 1410.

20 In block 1410 a batch of locally authorized transactions is data communicated to a remote location (the remote location being another country) by way of a network connection. In this regard locally authorized transactions can be moved from the country in which the vending sale occurred to the country where the transactions will be processed with a processing center. Processing then moves to block 1412. The transfer of locally authorized transactions can occur at a predetermined time including hourly, daily, weekly, monthly, or other desirable time interval.

25 In block 1412 the server receiving the locally authorized transactions from a plurality of remotely located system 500 authorizes and settles each locally authorized transaction. The process of settlement effectuates the transfer of funds from the cardholder to the merchant. In this regard, the transaction is authorized and settled in the

same country currency avoiding any currency conversion fees. Additionally, since transactions can be aggregated from a plurality of system 500 in a plurality of countries the transaction and currency volumes increase. These increases in transaction volumes coupled with efficient batching of transactions to the processing bureau can result in the lowest possible standard transaction processing fees. Processing then moves to block 1414.

In block 1414 the funds generated from the authorization and settlement of the locally authorized transaction can be electronically transferred back to a bank in the country in which the vending sale occurred, or the country of choice. Such a transfer can be accomplished by an electronic funds transfer (EFT), or other similar or desirable method for transfer funds. The transfer of funds can occur at a predetermined time including hourly, daily, weekly, monthly, or other desirable time interval. Processing then moves to block 1416.

In block 1416 reporting requirements can be effectuated as required and electronically transmitted to the appropriate parties. Such a reporting cycle can be referred to as a remittance cycle and can be utilized by all parties having involvement in the transactions to among other things verify fund transfers, and monitor vending equipment operational efficiencies. The remittance cycle can occur at a predetermined time including hourly, daily, weekly, monthly, or other desirable time interval. The routine is then exited.

Referring to Figure 15 there is shown a data communication transaction message parsing routine 1500. In an exemplary embodiment system 500 can generate data and transactions relating to vending equipment DEX data, vending equipment MDB data, vend transaction data, financial transaction data, system 500 diagnostic data, and other types of data and transactions. While a system 500 has data communication access to a

remote host network center 808 the system 500 can data communicate the mixed batch or varying types and kinds of data to the host network center 808 servers. It is at the host network centers 808 that the data and transaction must be parsed and handled in different methods. Such parsing method can include forwarding data to a subsequent server,
5 storing data in a database, data processing to produce a new result and then acting on the resultant data, storing and forwarding transaction data including card transaction data for authorization and settlement, as well as implementing other methods for handle mixed batch data parsing. Processing begins in block 1502

10 In block 1502 a host data connection is initiated and established between the system 500 and the host network center 808. Such a data connection can be a dial-up connection, and Internet based connection, or other suitable data connections. Processing then moves to block 1504.

15 In block 1504 the system 500 terminal configuration data is exchanged between the system 500 and the host network servers. This terminal configuration data effectuates the ability to remotely manage the terminal operational parameters including the terminals firmware version form a remote host network center 808. Processing then moves to block 1506.

20 In block 1506 the host network server receives a data stream from the system 500. The data stream can comprise a mixed batch of operational data, marketing data, transaction data, and other types of data. Processing then moves to block 1508.

25 In block 1508 the server implements a series of parsing methods to identify and separate the different kinds of data and transactional information. Processing then move to block 1510.

In block 1510 the host network server stores the parsed data in a temporary data structure wherein each type and kind of data is uniquely identifiable. The data connection is terminated with the system 500 and the routine is exited.

5 Referring to Figure 16A-16B there is shown a determination of transaction completion routine 1600. In an exemplary embodiment once a transaction has been authorized and approved vending begins. In many vending applications multi-vends per transaction may be desirable. Routine 1600 can implement a method of determining when to allow a user to make an additional purchase and when not to. Processing begins
10 in block 1602.

In block 1602 the transaction is authorized. Transaction authorization can occur as disclosed in routines 1300 and 1400, or by other suitable methods. When a transaction has been approved and the vending equipment is being readied for vending, processing
15 moves to block 1606.

In block 1606 a MAXIMUM VEND ITEM LIMIT is determined and set. The MAXIMUM VEND ITEM LIMIT is the maximum number of items that can be vended on a single authorization. The MAXIMUM VEND ITEM LIMIT can be stored as part of
20 the system 500's terminal configuration file and remotely managed by way of the remote host network center 808. In an exemplary embodiment the MAXIMUM VEND ITEM LIMIT can range from one to ten items. Processing then moves to block 1610.

In block 1610 the AUTHORIZED VALUE LIMIT is determined and set. The
25 AUTHORIZED VALUE LIMIT is the maximum total sale amount a user has been authorized to purchase. The AUTHORIZED VALUE LIMIT can be stored as part of the system 500's terminal configuration file and remotely managed by way of the remote host network center 808. Processing then moves to block 1604.

In block 1604 the NO ACTIVITY TIMER LIMIT is determined and set. The NO ACTIVITY TIMER LIMIT is the maximum amount of time a user has to make the first vend. The NO ACTIVITY TIMER LIMIT can be stored as part of the system 500's terminal configuration file and remotely managed by way of the remote host network center 808. In an exemplary embodiment the NO ACTIVITY TIMER LIMIT can range from less than one minute to several minutes. Processing then moves to block 1608.

In block 1608 the RE-VEND TIMER LIMIT is determined and set. The RE-VEND TIMER LIMIT is the maximum amount of time a user has to make additional vends beyond the first vend. The RE-VEND TIMER LIMIT can be stored as part of the system 500's terminal configuration file and remotely managed by way of the remote host network center 808. In an exemplary embodiment the RE-VEND TIMER LIMIT can range from less than one minute to several minutes. Processing then moves to block 1620.

In block 1620 a vending session is started. Processing moves to decision block 1622.

In decision block 1622 a determination is made as to whether the NO ACTIVITY TIMER LIMIT has been reached. If the resultant is in the affirmative that is the NO ACTIVITY TIMER LIMIT has not reached the limit then processing moves to decision block 1624. If the resultant is in the negative that is the NO ACTIVITY TIME LIMIT has been reached then processing moves to block 1626.

In block 1626 the end session sequence is started. The end session sequence includes waiting for the vending equipment to complete any last vends, ending the

vending session, saving sales record data, optionally printing a receipt, and any other end sequence steps that may be required. The routine is then exited.

In decision block 1624 a determination is made as to whether the user has pressed the end transaction button. If the resultant is in the affirmative that is the user has pressed the end transaction button then processing moves to block 1626. If the resultant is in the negative that is the user has not pressed the end transaction button the processing moves to decision block 1628.

In decision block 1628 a determination is made as to whether a VEND REQUEST MDB command has been received from the vending equipment's VMC. If the resultant is in the affirmative that is the VEND REQUEST has been received then processing moves to block 1630. If the resultant is in the negative that is the VEND REQUEST command was not received then processing moves back to decision block 1622.

In block 1630 the VEND REQUEST command is processed and a VEND APPROVED or VEND DENIED response message is data communicated from the system 500 to the requesting VMC. Processing moves to decision block 1632.

In decision block 1632 a determination is made as to whether the MAXIMUM VEND ITEM LIMIT has been reached. If the resultant is in the affirmative that is the MAXIMUM VEND ITEM LIMIT has been reached then processing moves back to block 1626. If the resultant is in the negative that is the MAXIMUM VEND ITEM LIMIT has not been reached then processing moves to decision block 1634.

In decision block 1634 a determination is made as to whether the AUTHORIZED VALUE LIMIT has been reached. If the resultant is in the affirmative that is the

AUTHORIZED VALUE LIMIT has been reached then processing moves back to block 1626. If the resultant is in the negative that is the AUTHORIZED VALUE LIMIT has not been reached then processing moves to decision block 1638.

5 In decision block 1638 a determination is made as to whether the user has pressed the end transaction button. If the resultant is in the affirmative that is the user has pressed the end transaction button the processing moves back to block 1626. If the resultant is in the negative that is the user has not pressed the end transaction button then processing moves to block 1636.

10 In block 1636 the RE-VEND TIMER is reset to zero. Processing moves to block 1640.

15 In block 1640 a vending session is started. A vending session is started by sending the BEGIN SESSION MDB command to the vending equipment's VMC. Processing moves to decision block 1642.

20 In decision block 1642 a determination is made as to whether the RE-VEND TIMER has reached the RE-VEND TIMER LIMIT. If the resultant is in the affirmative that is the RE-VEND TIMER has reached the RE-VEND TIMER LIMIT the processing moves back to block 1626. If the resultant is in the negative that is the RE-VEND TIMER has been reached the RE-VEND TIMER LIMIT then processing moves to decision block 1646.

25 In decision block 1646 a determination is made as to whether the user has pressed the end transaction button. If the resultant is in the affirmative that is the user has pressed the end transaction button the processing moves back to block 1626. If the resultant is in

the negative that is the user has not pressed the end transaction button then processing moves to block 1644.

In decision block 1644 a determination is made as to whether a VEND REQUEST MDB command has been received from the vending equipment's VMC. If the resultant is in the affirmative that is the VEND REQUEST has been received then processing moves to block 1648. If the resultant is in the negative that is the VEND REQUEST command was not received then processing moves back to decision block 1642.

In block 1648 the VEND REQUEST command is processed and a VEND APPROVED or VEND DENIED response message is data communicated from the system 500 to the requesting VMC. Processing moves to back to decision block 1632.

Referring to Figure 17 there is shown a data communication sweeping, processing, and data forwarding routine 1700. In an exemplary embodiment the host network center 808 accumulates a plurality of different kinds of parsed data transaction in a temporary data structure. Such a parsing and temporary data structure can be implemented as disclosed in routine 1500. To move the data transactions from the temporary data structure a more permanent data structure and or host network sever routine 1700 can be implemented. Processing begins in block 1702.

In block 1702 the transaction store in the temporary data structure are swept into an operational database. Such an operational database can be implemented as a SQL database, ORACLE database, flat file database, DB2 database, and or a combination of different kinds and types of databases. Processing then moves to block 1704.

In block 1704 locally authorized transactions that have not been previously authorized are authorized with a processing bureau 804. This authorization after the vending sale has occurred can be referred to as post authorization. Processing then moves to block 1706.

5

In block 1706 any transactions including the previously post authorized transaction are settled with the processing bureau 804. The process of settlement effectuates the transfer of funds from the cardholder to the merchant. Settlement after the vending sale has occurred can be referred to as post settlement or post settle. Processing then moves to block 1708.

10

In block 1708 any refund transactions generated by the host network center customer service are processed. Refund transactions can occur when a previously settled transaction requires some portion of the sale amount be refunded to the cardholder. Customer service can generate a refund transaction by querying from an operation database the original transaction and then initiating a refund transaction based in part on the queried customer's original transaction. Processing then moves to block 1710.

15

In block 1710 data related to vending equipment DEX and MDB detail can be converted as required and data communicated to databases, and or other servers. The process of converting the DEX and MDB data can involve parsing and repackaging the data into a desired data warehousing interface format. Alternatively, the DEX and MDB data can be posted to a server where customers can by way of a network connection to the host network center 808 download the data.

20

25

In addition to the convert and forward functionality the data handled can be measured and counted as desired for the purpose of billing for the service of gather data from a remote system 500 and delivering the data to a customer's desired location.

Measurement and counting can include for example and not limitation measuring file and or data size, measuring the frequency the data is gathered, counting the number of times data is gathered and or forwarded, measuring access to the host network center 808, or by other suitable measurement and counting methods and or criteria. Processing moves to
5 block 1712.

In block 1712 the funds collected from the processing of transaction can remitted to the customer as required by EFT or other desirable method. The funds remitted can have service fees deducted from them such that their EFT amount is less than the total
10 processed transaction amount. In this regard customer will not have to be billed for services. The deducting of service fees from the flow of funds can eliminate the need to invoice a customer for service. The routine is then exited.

Referring to Figure 18A-18B there is shown a mimic MDB interface port routine
15 1800. In an exemplary embodiment the system 500 can serve as a MDB protocol conversion gateway. In this regard the system 500 can emulate and interpolate VMC MDB messages for a plurality of peripheral device. In addition, the system 500 can act as a MDB master or MDB slave device allowing the system 500 to support peripheral devices the VMC cannot. Routine 1800 implements the system 500 functionality to
20 support the MDB interface 518 and the mimic MDB interface 516. Processing begins in block 1802.

In block 1802 the VMC and system 500 exchange MDB message commands by way of the VMC MDB interface 902 and the system 500's MDB interface 518. The
25 system 500 can be referred to as terminal 500 or as the terminal. Processing moves to block 1804.

In block 1804 the terminal 500 decodes the MDB command message. Processing moves to decision block 1806.

In decision block 1806 a determination is made as to whether the MDB command message is a coin mechanism command message. If the resultant is in the affirmative that is the MDB command message is a coin mechanism MDB command message then processing moves to block 1808. If the resultant is in the negative that is then MDB command message is not a coin mechanism MDB command message then processing moves to decision block 1812.

In block 1808 the MDB command message is encoded and forwarded or passed by way of the mimic MDB interface 516 to the coin mechanism. Processing then moves to block 1810.

In block 1810 the system 500 by way of the mimic MDB interface 516 receives any response MDB message from the coin mechanism. As required the system 500 decodes and determines if the response message from the coin mechanism required encoded and forwarding or passing of the message to the VMC. As determined by the system 500 the message is selectively forwarded to the VMC upon processing returning to block 1802.

In decision block 1812 a determination is made as to whether the MDB command message is a bill acceptor command message. If the resultant is in the affirmative that is the MDB command message is a bill acceptor MDB command message then processing moves to block 1814. If the resultant is in the negative that is then MDB command message is not a bill acceptor MDB command message then processing moves to decision block 1818.

In block 1814 the MDB command message is encoded and forwarded or passed by way of the mimic MDB interface 516 to the bill acceptor processing then moves to block 1816.

5 In block 1816 the system 500 by way of the mimic MDB interface 516 receives any response MDB message from the bill acceptor. As required the system 500 decodes and determines if the response message from the bill acceptor required encoded and forwarding or passing of the message to the VMC. As determined by the system 500 the message is selectively forwarded to the VMC upon processing returning to block 1802.

10 In decision block 1818 a determination is made as to whether the MDB command message is a card reader or online module (OLM) command message. If the resultant is in the affirmative that is the MDB command message is a card reader or OLM MDB command message then processing moves to block 1820. If the resultant is in the negative that is then MDB command message is not a card reader or OLM MDB command message then processing moves to block 1822.

15 In block 1820 the MDB command message is decoded and the appropriate response to the VMC is initiated by the system 500. Processing moves back to block 20 1802.

25 In block 1822 the system 500 optionally sends as a master device a MDB command message to the peripherals interconnected with the mimic MDB interface 516. Such peripherals can include coin mechanism, bill acceptor or validator, or other peripherals on the mimic MDB interface 516. If the system 500 does not have a MDB command message to send processing moves back to block 1802. If the system 500 has a command message to send the command message is sent to the desired peripheral device and processing moves to block 1824.

In block 1824 the system 500 receives any device response messages resultant from the sent MDB message. Processing then moves to decision block 1828.

5 In decision block 1828 a determination is made as to whether any received message or data on the mimic MDB bus needs to be forwarded or passed to the VMC by way of the MDB interface 518. If the resultant is in the affirmative that is the system has a command message or data to send to the VMC processing moves to block 1830. If the resultant is in the negative that is the system 500 does not has a command message or
10 data to send to the VMC processing moves to block 1826.

In block 1826 the terminal system 500 can manage the data received from the peripheral device as required. Processing moves back block 1802.

15 In block 1830 the terminal system 500 responds to the VMC POLL command message and responds by passing the command message and or data from the peripheral device to the VMC. Processing moves back to block 1802.

20 While this invention has been described with reference to specific embodiments, it is not necessarily limited thereto. Accordingly, the appended claims should be construed to encompass not only those forms and embodiments of the invention specifically described above, but to such other forms and embodiments, as may be devised by those skilled in the art without departing from its true spirit and scope.
